Package 'Rfast'

February 16, 2023

Type Package

Title A Collection of Efficient and Extremely Fast R Functions

Version 2.0.7

Date 2023-02-15

Author Manos Papadakis, Michail Tsagris, Marios Dimitriadis, Stefanos Fafalios, Ioannis Tsamardinos, Matteo Fasiolo, Giorgos Borboudakis, John Burkardt, Changliang Zou, Kleanthi Lakiotaki and Christina Chatzipantsiou.

Maintainer Manos Papadakis <rfastofficial@gmail.com>

Depends R (>= 3.5.0), Rcpp (>= 0.12.3), RcppZiggurat

LinkingTo Rcpp (>= 0.12.3), RcppArmadillo

SystemRequirements C++17

BugReports https://github.com/RfastOfficial/Rfast/issues

URL https://github.com/RfastOfficial/Rfast

Description A collection of fast (utility) functions for data analysis. Column- and row-wise means, medians, variances, minimums, maximums, many t, F and G-square tests, many regressions (normal, logistic, Poisson), are some of the many fast functions. References: a) Tsagris M., Papadakis M. (2018). Taking R to its limits: 70+ tips. PeerJ Preprints 6:e26605v1 <doi:10.7287/peerj.preprints.26605v1>. b) Tsagris M. and Papadakis M. (2018). R topics documented:

Rfast-package 6
All k possible combinations from n elements 10
Analysis of covariance 11

Analysis of variance with a count variable . . . 12
Angular central Gaussian random values simulation . . . 13
ANOVA for two quasi Poisson regression models . . . 14
Apply method to Positive and Negative number . . . 15
Apply to each column a method under condition . . . 17
Backward selection regression . . . 18
BIC (using partial correlation) forward regression . . . 19
BIC forward regression with generalised linear models . . . 20
Binary search algorithm . . . 21
Binomial coefficient and its logarithm . . . 22
Bootstrap t-test for 2 independent samples . . . 23
Check if any column or row is fill with values . . . 24
Check if values are integers and convert to integer . . . 25
Check Namespace and Rd files . . . 26
Check whether a square matrix is symmetric . . . 29
Chi-square and G-square tests of (unconditional) indepdence . . . 30
Cholesky decomposition of a square matrix . . . 31
Circular or angular regression . . . 32
Circular-linear correlation . . . 33
Colum-wise cumulative operations (sum, prod, min, max) . . . 34
Column and row wise coefficients of variation . . . 35
Column and row-wise Any/All . . . 36
Column and row-wise means of a matrix . . . 37
Column and row-wise medians . . . 38
Column and row-wise nth smallest value of a matrix/vector . . . 39
Column and row-wise Order - Sort Indices . . . 41
Column and row-wise products . . . 42
Column and row-wise range of values of a matrix . . . 43
Column and row-wise ranks . . . 44
Column and row-wise Shuffle . . . 45
Column and row-wise sums of a matrix . . . 46
Column and row-wise tabulate . . . 47
Column and row-wise variances and standard deviations . . . 48
Column and rows-wise mean absolute deviations . . . 49
Column-row wise minima and maxima of two matrices . . . 50
Column-wise differences . . . 51
Column-wise kurtosis and skewness coefficients . . . 52
Column-wise matching coefficients . . . 53
Column-wise minimum and maximum . . . 54
Column-wise MLE of some univariate distributions . . . 55
Column-wise true/false value . . . 57
Column-wise uniformity Watson test for circular data . . . 58
Column-wise Yule's Y (coefficient of colligation) . . . 59
Convert a dataframe to matrix . . . 60
Convert R function to the Rfast's coresponding . . . 61
Correlation based forward regression . . . 62
Correlation between pairs of variables . . . 63
Correlations . . . 65

Covariance and correlation matrix . . . 66
Cox confidence interval for the ratio of two Poisson variables . . . 67
Cross-Validation for the k-NN algorithm . . . 68
Cross-Validation for the k-NN algorithm using the arc cosinus distance . . . 70
Deep copy . . . 72
Density of the multivariate normal and t distributions . . . 73
Design Matrix . . . 74
Diagonal Matrix . . . 75
Distance between vectors and a matrix . . . 76
Distance correlation . . . 77
Distance matrix . . . 78
Distance variance and covariance . . . 80
Eigenvalues and eigenvectors in high dimensional principal component analysis . . . 81
Empirical and exponential empirical likelihood tests for one sample . . . 82
Empirical and exponential empirical likelihood tests for two samples . . . 83
Energy distance between matrices . . . 85
Equality of objects . . . 86
Estimation of an AR(1) model . . . 87
Estimation of the Box-Cox transformation . . . 88
Exact t-test for 2 independent samples . . . 89
Exponential empirical likelihood for a one sample mean vector hypothesis testing . . . 90
Exponential empirical likelihood hypothesis testing for two mean vectors . . . 91
Fast and general - untyped represantation of a factor variable . . . 93
FBED variable selection method using the correlation . . . 94
Find element . . . 95
Find the given value in a hash table . . . 96
Fitted probabilities of the Terry-Bradley model . . . 97
Fitting a Dirichlet distribution via Newton-Rapshon . . . 98
Floyd-Warshall algorithm . . . 99
Forward selection with generalised linear regression models . . . 101
G-square and Chi-square test of conditional indepdence . . . 102
Gamma regression with a log-link . . . 104
Gaussian regression with a log-link . . . 105
Generates random values from a normal and puts them in a matrix . . . 106
Get specific columns/rows fo a matrix . . . 107
Hash - Pair function . . . 108
Hash object . . . 109
Hash object to a list object . . . 110
High dimensional MCD based detection of outliers . . . 111
Hypothesis test for the distance correlation . . . 112
Hypothesis test for two means of percentages . . . 114
Hypothesis test for von Mises-Fisher distribution over Kent distribution . . . 115
Hypothesis testing between two skewness or kurtosis coefficients . . . 116
Index of the columns of a data.frame which are a specific type . . . 117
Insert/remove function names in/from the NAMESPACE file . . . 118
Inverse Gaussian regression with a log-link . . . 119
Inverse of a symmetric positive definite matrix . . . 120
Iterator . . . 121

James multivariate version of the t-test . . . 123
k nearest neighbours algorithm (k-NN) . . . 124
k-NN algorithm using the arc cosinus distance . . . 126
Limited number of eigenvalues and eigenvectors of a symmetric matrix . . . 127
Linear models for large scale data . . . 128
Logistic and Poisson regression models . . . 130
Logistic or Poisson regression with a single categorical predictor . . . 131
Lower and Upper triangular of a matrix . . . 133
Mahalanobis distance . . . 134
Many (and one) area under the curve values . . . 135
Many 2 sample proportions tests . . . 136
Many 2 sample tests . . . 137
Many analysis of variance tests with a discrete variable . . . 139
Many ANCOVAs . . . 140
Many ANOVAS for count data with Poisson or quasi Poisson models . . . 141
Many exponential regressions . . . 142
Many F-tests with really huge matrices . . . 143
Many G-square and Chi-square tests of indepedence . . . 144
Many Gini coefficients . . . 146
Many hypothesis tests for two means of percentages . . . 147
Many moment and maximum likelihood estimations of variance components . . . 148
Many multi-sample tests . . . 150
Many multivariate simple linear regressions coefficients . . . 151
Many non parametric multi-sample tests . . . 152
Many odds ratio tests . . . 154
Many one sample goodness of fit tests for categorical data . . . 155
Many one sample tests . . . 156
Many random intercepts LMMs for balanced data with a single identical covariate. . . . 157
Many regression based tests for single sample repeated measures . . . 159
Many score based regressions . . . 161
Many Shapiro-Francia normality tests . . . 163
Many simple circular or angular regressions . . . 164
Many simple geometric regressions . . . 165
Many simple linear mixed model regressions . . . 166
Many simple linear regressions coefficients . . . 167
Many simple multinomial regressions . . . 168
Many simple regressions for positive valued data . . . 169
Many tests for the dispersion parameter in Poisson distribution . . . 171
Many two-way ANOVAs . . . 172
Many univariate generalised linear models . . . 173
Many univariate simple linear regressions . . . 175
Many univariate simple logistic and Poisson regressions . . . 176
Many univariate simple quasi poisson regressions . . . 178
Many Welch's F-tests . . . 179
Match . . . 180
Matrix multiplication . . . 181
Matrix with all pairs of t-tests . . . 182
Matrix with G-square tests of indepedence . . . 183

Mean - Median absolute deviation of a vector . . . 185
Median of a vector . . . 186
Minima and maxima of two vectors/matrices . . . 187
Minimum and maximum . . . 188
Minimum and maximum frequencies . . . 189
MLE for multivariate discrete data . . . 190
MLE of (hyper-)spherical distributions . . . 191
MLE of continuous univariate distributions defined on the positive line . . . 193
MLE of continuous univariate distributions defined on the real line . . . 195
MLE of count data (univariate discrete distributions) . . . 196
MLE of distributions defined in the (0, 1) interval . . . 198
MLE of some circular distributions . . . 200
MLE of the inverted Dirichlet distribution . . . 201
MLE of the multivariate (log-) normal distribution . . . 202
MLE of the multivariate t distribution . . . 204
MLE of the ordinal model without covariates . . . 205
MLE of the tobit model . . . 206
Moment and maximum likelihood estimation of variance components . . . 207
Multi-sample tests for vectors . . . 209
Multinomial regression . . . 211
Multivariate kurtosis . . . 212
Multivariate Laplace random values simulation . . . 213
Multivariate normal and t random values simulation . . . 214
Naive Bayes classifiers . . . 215
Natural Logarithm each element of a matrix . . . 217
Natural logarithm of the beta function . . . 218
Natural logarithm of the gamma function and its derivatives . . . 219
Norm of a matrix . . . 220
Number of equal columns between two matrices . . . 221
Odds ratio and relative risk . . . 222
One sample t-test for a vector . . . 223
Operations between two matrices or matrix and vector . . . 224
Orthogonal matching pursuit variable selection . . . 226
Outer function . . . 227
Permutation . . . 228
Permutation based p-value for the Pearson correlation coefficient . . . 229
Polyserial correlation . . . 230
Pooled covariance matrix . . . 232
Prediction with some naive Bayes classifiers . . . 233
Quasi binomial regression for proportions . . . 234
Quasi Poisson regression for count data . . . 236
Random intercepts linear mixed models . . . 237
Random values simulation from a von Mises distribution . . . 239
Ranks of the values of a vector . . . 240
Reading the files of a directory . . . 241
Repeated measures anova . . . 242
Replicate columns/rows . . . 243
Represantation of Stack . . . 244

Round each element of a matrix/vector . . . 245
Row - Wise matrix/vector count the frequency of a value . . . 246
Row-wise minimum and maximum . . . 247
Row-wise true value . . . 248
Search for variables with zero range in a matrix . . . 249
Significance testing for the coefficients of Quasi binomial or the quasi Poisson regression 250
Simulation of random values from a Bingham distribution . . . 252
Simulation of random values from a Bingham distribution with any symmetric matrix . . . 253
Simulation of random values from a normal distribution . . . 254
Simulation of random values from a von Mises-Fisher distribution . . . 255
Skeleton of the PC algorithm . . . 256
Skewness and kurtosis coefficients . . . 258
Some summary statistics of a vector for each level of a grouping variable . . . 259
Sort - Integer Sort - Sort a vector coresponding to another . . . 260
Sort and unique numbers . . . 262
Sorting of the columns-rows of a matrix . . . 263
Source many R files . . . 264
Spatial median for Euclidean data . . . 265
Spatial median regression . . . 266
Spatial sign covariance matrix . . . 267
Spherical and hyperspherical median . . . 268
Standardisation . . . 269
Sub-matrix . . . 270
Sum of all pairwise distances in a distance matrix . . . 271
Table Creation - Frequency of each value . . . 272
Tests for the dispersion parameter in Poisson distribution . . . 274
Topological sort of a DAG . . . 275
Transpose of a matrix . . . 276
Uniformity test for circular data . . . 277
Variance of a vector . . . 278
Vector allocation in a symmetric matrix . . . 279
Weibull regression model . . . 280
Yule's Y (coefficient of colligation) . . . 281

Index **283**

`Rfast-package` *Really fast R functions*

Description

A collection of Rfast functions for data analysis. Note 1: The vast majority of the functions accept matrices only, not data.frames. Note 2: Do not have matrices or vectors with have missing data (i.e NAs). We do no check about them and C++ internally transforms them into zeros (0), so you may get wrong results. Note 3: In general, make sure you give the correct input, in order to get the correct output. We do no checks and this is one of the many reasons we are fast.

Details

Package:	Rfast
Type:	Package
Version:	2.0.7
Date:	2023-02-15
License:	GPL-2

Maintainers

Manos Papadakis <papadakm95@gmail.com>

Note

Acknowledgments: We would like to acknowledge:

- Professor Kurt Hornik, Doctor Uwe Ligges (and the rest of R core team) for their invaluable help with this R package.
- Erich Studerus for his invaluable comments.
- Neal Fultz for his suggestions.
- Vassilis Vasdekis for his invaluable help with the random effects models.
- Marios Dimitriadis' work was funded by the Special Account for Research Funds of the University of Crete, Department of Computer Science.
- Phillip Si is greatly acknowledged for his help with the Floyd-Warshal algorithm.
- Keefe Murphy for his invaluable help with NEWS file and for his suggestions.
- Zacharias Papadovassilakis gave us the inspiration for the memory efficient version of the k-NN algorithm.
- Yannis Pantazis explained us how the orhtogonal matching pursuit works.
- Achim Zeileis for his help with the quasi Poisson regression models.
- Pedro J. Aphalo for finding a bug.
- Dimitris Kyriakis for finding a bug.
- Cyrille Conord for finding a bug.
- Aaron Robotham for finding a bug.
- Calvin Pan from the Department of Human Genetics at UCLA found a bug in the function glm_logistic and he is greatly acknowledged for that.
- Adam Muschielok from Rodenstock GmbH found a bug in the function vmf.mle and he is greatly acknowledged for that.
- Bret Presnell for detecting and correcting a bug in the function rvmf.
- Gabriel Hoffman for spotting a mistake in the fuction dirimultinom.mle.
- Lutz von der Burchard for spotting a bug in the function bic.corfsreg.

From now on the Rfast can be used in C++ via LinkingTo mechanism.

- The main namespace is "Rfast". Inside "Rfast" you will find two more namespaces, "vector" and "matrix".
- Namespace "vector" for calling functions using an Rcpp's or RcppArmadillo's vector.
- Namespace "matrix" for calling functions using an Rcpp's or RcppArmadillo's matrices.
- The signatures of the functions and the arguments are the same that are exported in R.

For namespace "vector" the functions that are available are:

1. median(x)
2. var(x, std = false, na_rm = false)
3. mad(x, method = "median", na_rm = false)
4. shuffle(x,engine = Engine(time(0)) // Engine by default is default_random_engine. You can use anyone from C++.

For namespace "matrix" the functions that are available are:

1. transpose(x)
2. matrix_multiplication(x,y)
3. colSort(x, descend = false, stable = false, parallel = false)
4. rowSort(x, descend = false, stable = false, parallel = false)
5. is_symmetric(x)
6. colMedian(x, na_rm = false, parallel = false)
7. rowMedian(x, na_rm = false, parallel = false)
8. colVars(x, std = false, na_rm = false, parallel = false)
9. rowVars(x, std = false, na_rm = false, parallel = false)
10. colMads(x, method = "median", na_rm = false, parallel = false)
11. rowMads(x, method = "median", na_rm = false, parallel = false)
12. colShuffle(x,engine = Engine(time(0)) // Engine by default is default_random_engine. You can use anyone from C++.
13. rowShuffle(x,engine = Engine(time(0)) // Engine by default is default_random_engine. You can use anyone from C++.

How to use it:

1. Just add in "LinkingTo" in your NAMESPACE file the "Rfast" or in Rstudio "//[[Rcpp::depends(Rfast)]]".
2. Include in your cpp files the header "Rfast.h" and enjoy!

`All k possible combinations from n elements`

All k possible combinations from n elements

Description

All k possible combinations from n elements.

Usage

```
comb_n(n, k,simplify=TRUE)
```

Arguments

`n`	A positive **INTEGER** number or a vector with numbers.
`k`	A positive integer number at most equal to n or at most equal to the length of n, if n is a vector.
`simplify`	A logical value for return List instead of matrix.

Value

A matrix with k columns and rows equal to the number of possible unique combinations of n with k elements. If simplify is set to TRUE then a list with k values where each value has length equal to the number of possible unique combinations of n with k elements.

Author(s)

See Also

`nth`, `colMaxs`, `colMins`, `colrange`

Examples

```
system.time( comb_n(20, 4) )
system.time( combn(20, 4) )
x <- rnorm(5)
res<-comb_n(x, 3)
```

`Analysis of covariance`

Analysis of covariance

Description

Analysis of covariance

Usage

```
ancova1(y, ina, x, logged = FALSE)
```

Arguments

`y`	A numerical vector with the data, the response variable.
`ina`	A numerical vector with 1s, 2s, 3s and so one indicating the two groups. Be careful, the function is desinged to accept numbers greater than zero.
`x`	A numerical vector whose length is equal to the number of rows of y. This is the covariate.
`logged`	Should the p-values be returned (FALSE) or their logarithm (TRUE)?

Details

Analysis of covariance is performed. No interaction between the factor and the covariate is tested. Only the main effects. The design need not be balanced. The values of ina need not have the same frequency. The sums of squares have been adjusted to accept balanced and unbalanced designs.

Value

A matrix with the test statistic and the p-value for the factor variable and the covariate.

See Also

ancovas, ftests, ttests, anova1

Examples

```
y <- rnorm(90)
ina <- rbinom(90, 2, 0.5) + 1
x <- rnorm(90)
system.time( a <- ancova1(y, ina, x) )
```

`Analysis of variance with a count variable`

Analysis of variance with a count variable

Description

Analysis of variance with a count variable.

Usage

```
poisson.anova(y, ina, logged = FALSE)
geom.anova(y, ina, type = 1, logged = FALSE)
quasipoisson.anova(y, ina, logged = FALSE)
```

Arguments

y	A numerical vector with discrete valued data, i.e. counts.
ina	A numerical vector with discrete numbers starting from 1, i.e. 1, 2, 3, 4,... or a factor variable. This is suppose to be a categorical predictor. If you supply a continuous valued vector the function will obviously provide wrong results.
type	This argument is for the geometric distribution. Type 1 refers to the case where the minimum is zero and type 2 for the case of the minimum being 1.
logged	Should the p-values be returned (FALSE) or their logarithm (TRUE)?

Details

This is the analysis of variance with Poisson or geometric distributed data. What we do is a log-likelihood ratio test. However, this is exactly the same as Poisson regression with a single predictor variable who happens to be categorical. Needless to say that this is faster function than the glm command in R. For the same purpose with a Bernoulli variable use g2Test. The quasinpoisson.anova is when in the glm function you specify family = quasipoisson. This is suitable for the case of over or under-dispersed data.

Value

A vector with two values, the difference in the deviances (or the scale difference in the case of quasi poisson) and the relevant p-value. The quasipoisson.anova also returns the estimate of the ϕ parameter.

Author(s)

Michail Tsagris

R implementation and documentation: Michail Tsagris <mtsagris@uoc.gr> and Manos Papadakis <papadakm95@gmail.com>.

See Also

`logistic.cat1`, `g2Test`, `poisson.anovas`, `anova`, `poisson_only`,`poisson.mle`

Examples

```
y <- rpois(300, 10)
ina <- rbinom(300, 3, 0.5) + 1
a1 <- poisson.anova(y, ina)
a2 <- glm(y ~ ina, poisson)

res<-anova(a2, test = "Chisq")

y <- rgeom(300, 0.7)
res<-geom.anova(y, ina)
```

`Angular central Gaussian random values simulation`

Angular central Gaussian random values simulation

Description

Angular central Gaussian random values simulation.

Usage

```
racg(n, sigma, seed = NULL)
```

Arguments

`n`	The sample size, a numerical value.
`sigma`	The covariance matrix in R^d.
`seed`	If you want the same to be generated again use a seed for the generator, an integer number.

Details

The algorithm uses univariate normal random values and transforms them to multivariate via a spectral decomposition. The vectors are then scaled to have unit length.

Value

A matrix with the simulated data.

Examples

```
s <- cov( iris[, 1:4] )
x <- racg(100, s)
res<-acg.mle(x)
res<-vmf.mle(x)  ## the concentration parameter, kappa, is very low, close to zero, as expected.
```

ANOVA for two quasi Poisson regression models

ANOVA for two quasi Poisson regression models

Description

ANOVA for two quasi Poisson regression models.

Usage

```
anova_quasipois.reg(mod0, mod1, n)
```

Arguments

mod0	An object as returned by the "qpois.reg" function. This is the null model.
mod1	An object as returned by the "qpois.reg" function. This is the alternative model.
n	The sample size. This is necessary to calculate the degrees of freedom.

Details

This is an ANOVA type significance testing for two quasi Poisson models.

Value

A vector with 4 elements, the test statistic value, its associated p-value and the relevant degrees of freedom of the numerator and the denominator.

anova_qpois.reg, qpois.reg, univglms, quasipoisson.anova

Examples

```
y <- rnbinom(200, 10, 0.5)
x <- matrix(rnorm(200 * 3), ncol = 3)
a1 <- qpois.reg(x, y)
a0 <- qpois.reg(x[, 1], y)
res<-anova_quasipois.reg(a0, a1, 200)
b1 <- glm(y ~ x, family = quasipoisson)
b0 <- glm(y ~ x[, 1], family = quasipoisson)
res<-anova(b0, b1, test = "F")
c1 <- glm(y ~ x, family = poisson)
c0 <- glm(y ~ x[, 1], family = poisson)
res<-anova(c0, c1, test = "Chisq")
```

`Apply method to Positive and Negative number`

Apply method to Positive and Negative number

Description

Apply method to Positive and Negative number.

Usage

```
negative(x,method = "min")
positive(x,method = "min")
positive.negative(x,method = "min")
```

Arguments

x	A numerical vector with data.
method	Accept 3 values. "min", "max", "min.max".

Details

These functions apply the chosen method to the chosen subset (negative, positive, or both) from the vector and return the result.

Value

negative: apply the chosen method to every negative number of the input vector. positive: apply the chosen method to every positive number of the input vector. positive.negative: apply the chosen method to every negative and positive number of the input vector.

identical(positive.negative(x,"min"), c(min(x<0),min(x>0)))

x<-NULL
```

`Apply to each column a method under condition`
Apply to each column a method under condition

Description

Apply to each column a method under condition.

Usage

```
apply.condition(x,method = "+",oper = ">",cond.val = 0)
```

Arguments

`x`	An integer matrix.
`method`	One of: "+", "-", "*", "min", "max".
`oper`	One of: ">, "<", ">=", "<=".
`cond.val`	An integer value for the condition.

Details

Apply to each col the specified method using the condition.

Value

An integer vector with the coresponding values.

Author(s)

Manos Papadakis and Michail Tsagris

R implementation and documentation: Manos Papadakis <papadakm95@gmail.com> and Michail Tsagris <mtsagris@uoc.gr>.

identical(apply(x,2,function(x){ sum(x[x>0]) }), apply.condition(x,"+",">",0))
x<-NULL
```

`Backward selection regression`
Backward selection regression

Description

Backward selection regression.

Usage

```
bs.reg(y, x, alpha = 0.05, type = "logistic")
```

Arguments

`y`	A numerical vector with the response variable values. It can either be of 0 and 1 values (Logistic regression) or of integer values 0, 1, 2,... (Poisson regression).
`x`	A numerical matrix with the candidate variables.
`alpha`	Threshold (suitable values are in [0,1]) for assessing the significance of p-values. The default value is at 0.05.
`type`	For the Logistic regression put "logistic" (default value) and for Poisson type "poisson".

Details

This function currently implements only the binary Logistic and Poisson regressions. If the sample size is less than the number of variables a notification message will appear and no backward regression will be performed.

Value

The output of the algorithm is an S3 object including:

`info`	A matrix with the non selected variables and their latest test statistics and p-values.
`Vars`	A vector with the selected variables.

```

`BIC (using partial correlation) forward regression`
BIC (using partial correlation) forward regression

Description

BIC (using partial correlation) forward regression.

Usage

```
bic.corfsreg(y, x, tol = 2)
```

Arguments

`y`	A numerical vector.
`x`	A matrix with data, the predictor variables.
`tol`	If the BIC difference between two successive models is less than the tolerance value, the variable will not enter the model.

Details

The forward regression tries one by one the variables using the F-test, basically partial F-test every time for the latest variable. This is the same as testing the significance of the coefficient of this latest enetered variable. Alternatively the correlation can be used and this case the partial correlation coefficient. There is a direct relationship between the t-test statistic and the partial correlation coefficient. Now, instead of having to calculate the test statistic, we calculate the partial correlation coefficient. The largest partial correlation indicates the candidate variable to enter the model. If the BIC of the regression model with that variable included, reduces, less than "tol" from the previous model without this variable, the variable enters.

Value

A matrix with two columns, the index of the selected variable(s) and the BIC of each model. The first line is always 0 and the BIC of the model with no predictor variables.

system.time( a2 <- cor.fsreg(y, x) )
x <- NULL
```

BIC forward regression with generalised linear models

BIC forward regression with generalised linear models

Description

BIC forward regression with generalised linear models.

Usage

```
bic.fs.reg(y, x, tol = 2, type = "logistic")
```

Arguments

y	A numerical vector.
x	A matrix with data, the predictor variables.
tol	If the BIC difference between two successive models is less than the tolerance value, the variable will not enter the model.
type	If you have a binary dependent variable, put "logistic". If you have count data, put "poisson".

Details

The forward regression tries one by one the variables using the BIC at each step for the latest variable. If the BIC of the regression model with that variable included, is less than "tol" from the previous model without this variable, the variable enters.

Value

A matrix with two columns, the index of the selected variable(s) and the BIC of each model.

x <- NULL
```

`Binary search algorithm`

Binary search algorithm

Description

Search a value in an ordered vector.

Usage

```
binary_search(x, v, index=FALSE)
```

Arguments

x	A vector with the data.
v	A value to check if exists in the vector x.
index	A boolean value for choose to return the position inside the vector.

Details

The functions is written in C++ in order to be as fast as possible.

Value

Search if the v exists in x. Then returns TRUE/FALSE if the value is been found.

Author(s)

Manos Papadakis

R implementation and documentation: Manos Papadakis <papadakm95@gmail.com>.

Examples

```
x <- sort(rnorm(1000))
v <- x[50]
b <- binary_search(x,v)
b1 <- binary_search(x,v,TRUE)
```

Binomial coefficient and its logarithm

Binomial coefficient and its logarithm

Description

Binomial coefficient and its logarithm.

Usage

```
Lchoose(x, k)
Choose(x, k)
```

Arguments

x	A vector with integer values numbers.
k	A positive non zero at most equal to x.

Details

The binomial coefficient or its logarithm are evaluated.

Value

A vector with the answers.

Author(s)

Manos Papadakis

R implementation and documentation: Michail Tsagris <mtsagris@uoc.gr>

```

`Bootstrap t-test for 2 independent samples`
Bootstrap t-test for 2 independent samples

Description

Bootstrap t-test for 2 independent samples.

Usage

```
boot.ttest2(x, y, B = 999)
```

Arguments

x	A numerical vector with the data.
y	A numerical vector with the data.
B	The number of bootstrap samples to use.

Details

Instead of sampling B times from each sample, we sample $\sqrt{B}$ from each of them and then take all pairs. Each bootstrap sample is independent of each other, hence there is no violation of the theory.

Value

A vector with the test statistic and the bootstrap p-value.

```

Check if any column or row is fill with values

Check if any column or row is fill with values

Description

Check if any column or row is fill with values.

Usage

```
colrow.value(x,value=0)
```

Arguments

x	A vector with data.
value	A value to check.

Details

Check all the column if any has all its elements equal to argument value. If found, return "TRUE". Otherwise continues with rows. If columns and rows hasn't any value vector then return "FALSE". Even if it returns "FALSE" that doesn't mean the determinant can't be value. It might be but if check before and found any value vector then for sure the determinant it'll be value.

Value

A boolean value, "TRUE" if any column OR row is all filled with value. "FALSE" otherwise.

x<-NULL
```

`Check if values are integers and convert to integer`

Check if values are integers and convert to integer

Description

Check if values are integers and convert to integer.

Usage

```
is_integer(x)
as_integer(x,result.sort = TRUE,init = 1)
```

Arguments

`x`	is_integer: A vector with numeric data. as_integer: A vector with data.
`result.sort`	A logical value for sorting the result.
`init`	An integer value to start.

Details

The behavior of these functions are different than R's built in.

is_integer: check if all the values are integers in memory. If typeof is double, and the values are integers in range -2^31 : 2^31 then it is better to convert to integer vector for using less memory. Also you can decrease the time complexity.

as_integer: converts the discrete values to integers.

Value

is_integer: A logical value, TRUE if all values are integers and in range -2^31 : 2^31. Otherwise FALSE.

as_integer: By default the function will return the same result with "as.numeric" but the user can change the "init" value not start from 1 like R's. Also the result can be unsorted using "result.sort".

Author(s)

R implementation and documentation: Manos Papadakis <papadakm95@gmail.com>.

See Also

as_integer, colVars, colmeans, read.directory

Examples

```
x<-runif(10)
y1<-is_integer(x) # y1 is FALSE
x<-as.numeric(rpois(10,10)) # integers but typeof is double
y1<-is_integer(x) # y1 is TRUE so you can convert to integer vector.

as_integer(letters) ## as.numeric(letters) produce errors
x<-y1<-NULL
```

Check Namespace and Rd files

Check Namespace and Rd files

Description

Check Namespace/Rd and examples files.

Usage

```
checkNamespace(path.namespace,path.rfolder)
checkAliases(path.man,path.rfolder)
checkTF(path.man)
checkExamples(path.man,each = 1,print.errors = stderr(),
print.names = FALSE)
checkUsage(path.man,path.rfolder)
```

Arguments

path.namespace	An full path to the "NAMESPACE" file.
path.rfolder	An full path to the directory that contains the "R" files.
path.man	An full path to the directory that contains the "Rd" files.

`each`	An integer value for running **each** example.
`print.errors`	Print the errors to a file. By default it's "stderr()".
`print.names`	A boolean value (TRUE/FALSE) for printing the names of the files before running the examples.

Details

For function "checkNamespace": reads from the NAMESPACE folder all the export R functions, reads from folder R all the R functions and check if all the functions are export.

For function "checkAliases": reads from the man directory all the Rd files, then reads from each file the aliases and check if: 1) All the R files has man file or an alias. 2) All aliases belongs to functions. 3) If there are dublicated aliases.

For function "checkExamples": reads from the man directory all the Rd files, then read from each file the examples and then run each of them. If you want to print the errors in any file then set "print.errors=file_name" or in the standard error "print.errors=stderr()" and then you will see all the errors for every file. For succeed run of your code you should first run "library(PACKAGE_NAME)". The argument "print.names" it is very helpful because if any of you function crashes R during running you will never know which one was. So setting it "TRUE", it will print the name of each file before runnign it's example.It might crash, but you will know which file. **Remember that there is always an error timeout so it might didn't crash the current file but one from the previous.**

For function checkTF: reads from the man directory all the Rd files, then read from each file the examples and checks if any examples has the values "T" and "F" instead "TRUE" and "FALSE". The "T","F" is wrong.

For function checkUsage: reads from the man directory all the Rd files and for each man check if the usage section has the right signature for the functions from the R directory.

For functions "checkTF", "checkUsage", "checkAliases" you can choose which files not to read for both R and Rd. You must add in the first line of the file in comment the "attribute" "[dont read]". Then each function will know which file to read or not. For Rd you add "%[dont read]" and for R "#[dont read]". Finally, these functions will return in the result a list of which files had this attribute.

Value

For function "checkNamespace": a vector with the names of missing R files. (Don't use it for now)

For function "checkAliases": a list with 4 fields.

`Missing Man files`	A vector with the names of the missing Rd files or nothing.
`Missing R files`	A vector with the names of the missing R files or nothing.
`Duplicate alias`	A vector with the names of the dublicate aliases or nothing.
`dont read`	A list with 2 fields R: A character vector whith the names of the files that had attribute "#[dont read]" or nothing. Rd: A character vector whith the names of the files that had attribute "%[dont read]" or nothing.

For function "checkExamples": a list with 3 fields

`Errors`	A character vector with the names of the Rd files that produced an error.

`Big Examples` A character vector with the names of the Rd files that has big examples per line.

`dont read` A list with 2 fields R: A character vector whith the names of the files that had attribute "#[dont read]" or nothing. Rd: A character vector whith the names of the files that had attribute "%[dont read]" or nothing.

For function "checkTF": a list with 3 fields

`TRUE` A character vector with the names of the Rd files that has "T" or nothing.

`FALSE` A character vector with the names of the Rd files that has "F" or nothing.

`dont read` A list with 2 fields R: A character vector whith the names of the files that had attribute "#[dont read]" or nothing. Rd: A character vector whith the names of the files that had attribute "%[dont read]" or nothing.

For function "checkUsage": a list with 3 fields

`missing functions`
A character vector with the name of the file that is missing and the Rd file that is found or nothing.

`missmatch functions`
A character vector with the name of the file that has missmatch function and the Rd file that is found or nothing.

`dont read` A list with 2 fields R: A character vector whith the names of the files that had attribute "#[dont read]" or nothing. Rd: A character vector whith the names of the files that had attribute "%[dont read]" or nothing.

`hidden functions`
A character vector with the name of the functions thath have been declared as hidden.

`Check whether a square matrix is symmetric`
Check whether a square matrix is symmetric

Description

Check whether a square matrix is symmetric.

Usage

```
is.symmetric(x)
```

Arguments

`x`	A square matrix with data.

Details

Instead of going through the whole matrix, the function will stop if the first disagreement is met.

Value

A boolean value, TRUE of FALSE.

Author(s)

Manos Papadakis

R implementation and documentation: Manos Papadakis <papadakm95@gmail.com>.

is.symmetric(x)

x<-s1<-NULL
```

Chi-square and G-square tests of (unconditional) indepdence

Chi-square and G-square tests of (unconditional) indepdence

Description

Chi-square and G-square tests of (unconditional) indepdence.

Usage

```
gchi2Test(x, y, logged = FALSE)
```

Arguments

x	A numerical vector or a factor variable with data. The data must be consecutive numbers.
y	A numerical vector or a factor variable with data. The data must be consecutive numbers.
logged	Should the p-values be returned (FALSE) or their logarithm (TRUE)?

Details

The function calculates the test statistic of the χ^2 and the G^2 tests of unconditional independence between x and y. x and y need not be numerical vectors like in g2Test. This function is more close to the spirit of MASS' loglm function which calculates both statistics using Poisson log-linear models (Tsagris, 2017).

Value

A matrix with two rows. In each row the X2 or G2 test statistic, its p-value and the degrees of freedom are returned.

Author(s)

Manos Papadakis and Michail Tsagris

R implementation and documentation: Manos Papadakis <papadakm95@gmail.com> and Michail Tsagris <mtsagris@uoc.gr>.

res<-gchi2Test(data[, 1], data[, 2])
res<-g2Test_univariate( data, rep(3, 2) )  ## G^2 test
res<-chisq.test(data[, 1], data[, 2])  ## X^2 test from R

data<-NULL
```

`Cholesky decomposition of a square matrix`
Cholesky decomposition of a square matrix

Description

Cholesky decomposition of a square matrix.

Usage

```
cholesky(x,parallel = FALSE)
```

Arguments

`x`	A square positive definite matrix.
`parallel`	A boolean value for parallel version.

Details

The Cholesky decomposition of a square positive definite matrix is computed. The use of parallel is suggested for matrices with dimensions of 1000 or more.

Value

An upper triangular matrix.

all.equal(a1[upper.tri(a1)], a2[upper.tri(a2)])
x <- NULL
s <- NULL
a1 <- NULL
a2 <- NULL
```

Circular or angular regression

Circular or angular regression

Description

Regression with circular dependent variable and Euclidean or categorical independent variables.

Usage

```
spml.reg(y, x, tol = 1e-07, seb = FALSE, maxiters = 100)
```

Arguments

y	The dependent variable, it can be a numerical vector with data expressed in radians or it can be a matrix with two columns, the cosinus and the sinus of the circular data. The benefit of the matrix is that if the function is to be called multiple times with the same response, there is no need to transform the vector every time into a matrix.
x	The independent variable(s). Can be Euclidean or categorical (factor variables).
tol	The tolerance value to terminatate the Newton-Raphson algorithm.
seb	Do you want the standard error of the estimates to be returned? TRUE or FALSE.
maxiters	The maximum number of iterations to implement.

Details

The Newton-Raphson algorithm is fitted in this regression as described in Presnell et al. (1998).

Value

A list including:

iters	The number of iterations required until convergence of the EM algorithm.
be	The regression coefficients.

seb	The standard errors of the coefficients.
loglik	The value of the maximised log-likelihood.
seb	The covariance matrix of the beta values.

y <- y / sqrt( rowsums(y^2) )
a1 <- spml.reg(y, x)
y <- atan( y[, 2] / y[, 1] ) + pi * I(y[, 1] < 0)
a2 <- spml.reg(y, x)
```

Circular-linear correlation

Circular-linear correlation

Description

It calculates the squared correlation between a circular and one or more linear variables.

Usage

```
circlin.cor(theta, x)
```

Arguments

theta	A circular variable expressed in radians.
x	The linear variable or a matrix containing many linear variables.

Details

The squared correlation between a circular and one or more linear variables is calculated.

Value

A matrix with as many rows as linear variables including:

R-squared	The value of the squared correlation.
p-value	The p-value of the zero correlation hypothesis testing.

Colum-wise cumulative operations (sum, prod, min, max)

Colum-wise cumulative operations (sum, prod, min, max)

Description

Colum-wise cumulative operations (sum, prod, min, max).

Usage

```
colCumSums(x)
colCumProds(x)
colCumMins(x)
colCumMaxs(x)
```

Arguments

x	A numerical matrix.

Details

Cumulative mins, maxs, sums and prods are returned.

Value

A matrix with the results. It has one row less than the initial matrix.

Column and row wise coefficients of variation

Column and row wise coefficients of variation

Description

Column and row wise coefficients of variation.

Usage

```
colcvs(x, ln = FALSE, unbiased = FALSE)
rowcvs(x, ln = FALSE, unbiased = FALSE)
```

Arguments

x	A numerical matrix with the data.
ln	If you have log-normally distributed data (or assume you do), then set this to TRUE.
unbiased	A boolean variable indicating whether the unbiased for shpould be returned. This is applicable in case of small samples.

Details

The colum-wise coefficients of variation are calculated.

Value

A vector with the coefficient of variation for each column or row.

Column and row-wise Any/All

Column and row-wise Any

Description

Column and row-wise Any/All of a matrix.

Usage

```
colAny(x)
rowAny(x)
colAll(x, parallel = FALSE)
rowAll(x, parallel = FALSE)
```

Arguments

x	A logical matrix with the data.
parallel	Do you want the computations to take place in parallel? The default value is FALSE.

Details

The functions is written in C++ in order to be as fast as possible.

Value

A vector where item "i" is true if found Any/All true in column/row "i". Otherwise false.

all.equal(a,b)

a<-b<-x<-NULL
```

`Column and row-wise means of a matrix`

Column and row-wise means of a matrix

Description

Column and row-wise means of a matrix.

Usage

```
colmeans(x, parallel = FALSE)
## S3 method for class 'matrix'
colmeans(x, parallel = FALSE)
## S3 method for class 'data.frame'
colmeans(x, parallel = FALSE)
rowmeans(x)
colhameans(x, parallel = FALSE)
rowhameans(x)
```

Arguments

x	A numerical matrix or data.frame with data.
parallel	Do you want to do it in parallel in C++? TRUE or FALSE.

Value

A vector with the column or row arithmetic or harmonic means.

Author(s)

Manos Papadakis

R implementation and documentation: Manos Papadakis <papadakm95@gmail.com>.

Examples

```
x <- matrix(rpois(100 * 100, 10),ncol = 100)
x1 <- colmeans(x)
x2 <- colMeans(x)
all.equal(x1,x2)

x1 <- rowmeans(x)
x2 <- rowMeans(x)
all.equal(x1,x2)
system.time( colhameans(x) )
system.time( rowhameans(x) )

x<-x1<-x2<-NULL
```

Column and row-wise medians

Column and row-wise medians

Description

Column and row-wise medians of a matrix.

Usage

```
colMedians(x,na.rm = FALSE, parallel = FALSE)
rowMedians(x,na.rm = FALSE, parallel = FALSE)
```

Arguments

x	A matrix with the data.
parallel	Do you want to do it in parallel in C++? TRUE or FALSE.
na.rm	TRUE or FAlSE for remove NAs if exists.

Details

The functions is written in C++ in order to be as fast as possible.

Value

A vector with the column medians.

Author(s)

R implementation and documentation: Manos Papadakis <papadakm95@gmail.com>.

See Also

Median, colVars, colMeans (buit-in R function)

Examples

```
x <- matrix( rnorm(100 * 100), ncol = 100 )
a <- apply(x, 2, median)
b1 <- colMedians(x)
all.equal(as.vector(a), b1)

x<-a<-b1<-NULL
```

Column and row-wise nth smallest value of a matrix/vector

Column and row-wise nth smallest value of a matrix/vector

Description

Column and row-wise nth smallest value of a matrix/vector.

Usage

```
colnth(x,elems, num.of.nths = 1,descending = FALSE,na.rm = FALSE,
index.return = FALSE, parallel = FALSE)
rownth(x,elems, num.of.nths = 1,descending = FALSE,na.rm = FALSE,
index.return = FALSE, parallel = FALSE)
nth(x, k, num.of.nths = 1,descending = FALSE,index.return = FALSE,na.rm = FALSE)
```

Arguments

x	A matrix with the data.
elems	An integer vector with the kth smallest number to be returned for each column/row.
k	The kth smallest/biggest number to be returned.
num.of.nths	The number of the returned nths. By default is 1. Not use with argument parallel, for now.
descending	A boolean value (TRUE/FALSE) for descending order (biggest number). By default is ascending (smallest number).
index.return	Return the index of the kth smallest/biggest number.
parallel	Do you want to do it in parallel in C++? TRUE or FALSE only for col-row wise.
na.rm	TRUE or FAlSE for remove NAs if exists. Only for function "nth".

Details

The functions is written in C++ in order to be as fast as possible.

Value

For "colnth" , "rownth": A vector with the column/row nth

For "nth": The nth value.

Author(s)

Manos Papadakis <papadakm95@gmail.com>

R implementation and documentation: Michail Tsagris <mtsagris@uoc.gr> and Manos Papadakis <papadakm95@gmail.com>.

See Also

Median, colMedians, colMeans (buit-in R function)

Examples

```
x <- matrix( rnorm(100 * 100), ncol = 100 )
elems <- sample(1:100,100,TRUE)
system.time( colnth(x,elems) )
system.time( rownth(x,elems) )
x <- rnorm(1000)
nth(x, 500)
sort(x)[500]

x<-elems<-NULL
```

`Column and row-wise Order - Sort Indices`
Column and row-wise Order - Sort Indices

Description

Column and row-wise Order - Sort Indices.

Usage

```
colOrder(x,stable=FALSE,descending=FALSE, parallel = FALSE)
rowOrder(x,stable=FALSE,descending=FALSE, parallel = FALSE)
Order(x,stable=FALSE,descending=FALSE,partial = NULL)
```

Arguments

`x`	A matrix with numbers or a numeric/character vector.
`stable`	A boolean value for using a stable sorting algorithm.
`descending`	A boolean value (TRUE/FALSE) for sorting the vector in descending order. By default sorts the vector in ascending.
`parallel`	A boolean value for parallel version.
`partial`	A boolean value for partial sorting.

Details

The function applies "order" in a column or row-wise fashion or Order a vector. If you want the same results as R's, then set "stable=TRUE" because "stable=FALSE" uses a sorting algorithm that it is not stable like R's sort. But it is faster to use the default. This verion is faster for large data, more than 300.

Value

For "colOrder" and "rowOrder" a matrix with integer numbers. The result is the same as apply(x, 2, order) or apply(x, 1, order).

For "Order" sort the vector and returns the indices of each element that it has before the sorting. The result is the same as order(x) but for the same exactly results set argument "stable" to "TRUE".

```
x <- matrix( runif(10 * 10), ncol = 10 )
res<-colOrder(x)
res<-apply(x, 2, order)
res<-rowOrder(x)
t(apply(x, 1, order))

y <- rnorm(100)
b <- Order(y)
a <- order(y)
all.equal(a,b) ## false because it is not stable
b <- Order(y,stable=TRUE)
all.equal(a,b) ## true because it is stable

x<-y<-b<-a<-NULL
```

Column and row-wise products

Column and row-wise products

Description

Column and row-wise products.

Usage

```
colprods(x, method = "direct")
rowprods(x)
```

Arguments

x	A matrix with numbers.
method	The type of colCumProds to use. For direct multiplication use "direct" or "expsumlog" for a more numerically stable, but slower way.

Details

The product of the numbers in a matrix is returned either column-wise or row-wise.

Value

A vector with the column or the row products.

Author(s)

Manos Papadakis

R implementation and documentation: Manos Papadakis <papadakm95@gmail.com>.

See Also

colsums, coldiffs, colMedians

Examples

```
x <- matrix( runif(100 * 10), ncol = 10 )

```

`Column and row-wise range of values of a matrix`

Column and row-wise range of values of a matrix.

Description

Column and row-wise range of values of a matrix.

Usage

```
colrange(x, cont = TRUE)
rowrange(x, cont = TRUE)
```

Arguments

`x`	A numerical matrix with data.
`cont`	If the data are continuous, leave this TRUE and it will return the range of values for each variable (column). If the data are integers, categorical, or if you want to find out the number of unique numbers in each column set this to FALSE.

Value

A vector with the relevant values.

Author(s)

Manos Papadakis

R implementation and documentation: Manos Papadakis <papadakm95@gmail.com>.

colMins, colMaxs, rowMins, rowMaxs, nth, colMedians, colVars, colSort, rowSort

Examples

```
x <- matrix( rnorm(100 * 100), ncol = 100 )

a1 <- colrange(x)
a2 <- apply(x, 2, function(x) diff( range(x)) )
all.equal(a1, a2)

a1 <- rowrange(x)
a2 <- apply(x, 1, function(x) diff( range(x)) )
all.equal(a1, a2)

x<-a1<-a2<-NULL
```

Column and row-wise ranks

Column and row-wise ranks

Description

Column and row-wise ranks.

Usage

```
colRanks(x,method = "average",descending = FALSE,stable = FALSE, parallel = FALSE)
rowRanks(x,method = "average",descending = FALSE,stable = FALSE, parallel = FALSE)
```

Arguments

x	A mumerical matrix with the data.
parallel	A boolean value for parallel version.
method	a character string for choosing method. Must be one of "average", "min", "max", "first".
descending	A boolean value (TRUE/FALSE) for sorting the vector in descending order. By default sorts the vector in ascending.
stable	A boolean value (TRUE/FALSE) for choosing a stable sort algorithm. Stable means that discriminates on the same elements. Only for the method "first".

Details

For each column or row of a matrix the ranks are calculated and they are returned. The initial matrix is gone.

Value

A matrix with the column or row-wise ranks.

Author(s)

Manos Papadakis

R implementation and documentation: Manos Papadakis <papadakm95@gmail.com>.

See Also

`Rank`, `correls`

Examples

x <- matrnorm(100, 10)
a1 <- colRanks(x)
a2 <- apply(x, 2, rank)
b1 <- rowRanks(x)
b2 <- apply(x, 1, rank)

x<-a1<-a2<-b1<-b2<-NULL
```

`Column and row-wise Shuffle`

Column and row-wise Shuffle

Description

Column and row-wise shuffle of a matrix.

Usage

```
colShuffle(x)
rowShuffle(x)
```

Arguments

`x`	A matrix with the data.

Details

The functions is written in C++ in order to be as fast as possible.

Value

A vector with the column/row Shuffle.

Author(s)

R implementation and documentation: Manos Papadakis <papadakm95@gmail.com>.

See Also

Median, colVars, colMeans (buit-in R function)

Examples

system.time( rowShuffle(x) )

x<-NULL
```

Column and row-wise sums of a matrix

Column and row-wise sums of a matrix

Description

Column and row-wise sums of a matrix.

Usage

```
colsums(x,indices = NULL, parallel = FALSE, na.rm = FALSE)

rowsums(x,indices = NULL, parallel = FALSE, na.rm = FALSE)
```

Arguments

x	A numerical matrix with data.
indices	An integer vector with the indices to sum the columns/rows.
parallel	Do you want to do it in parallel in C++? TRUE or FALSE. Doens't work with argument "indices".
na.rm	A logical value indicating to remove NAs. The algorithm run in parallel so do not use with option parallel.

Value

A vector with sums.

Author(s)

Manos Papadakis

R implementation and documentation: Manos Papadakis <papadakm95@gmail.com>.

See Also

colMedians, colmeans, colVars

Examples

```
x <- matrix(rpois(500 * 100, 10),ncol = 100)
x1 <- colsums(x)
x2 <- colSums(x)
all.equal(x1,x2)

x1 <- rowsums(x)
x2 <- rowSums(x)
all.equal(x1,x2)

x<-x1<-x2<-NULL
```

`Column and row-wise tabulate`

Column and row-wise tabulate

Description

Column and row-wise tabulate of a matrix.

Usage

```
colTabulate(x, max_number = max(x))
rowTabulate(x, max_number = max(x))
```

Arguments

`x`	An integer matrix with the data. The numbers must start from 1, i.e. 1, 2, 3, 4,... No zeros are allowed. Anything else may cause a crash.
`max_number`	The maximum value of vector x. If you know which is the max number use this argument for faster results or by default max(x).

Details

The functions is written in C++ in order to be as fast as possible.

Value

A matrix where in each column the command "tabulate" has been performed. The number of rows of the returned matrix will be equal to the max_number if given. Otherwise, the functions will find this number.

Author(s)

R implementation and documentation: Manos Papadakis <papadakm95@gmail.com>.

See Also

`colShuffle`, `colVars`, `colmeans`

Examples

```
x <- matrix( rbinom(100 * 100, 4, 0.5), ncol = 100 )

x <- t(x)
system.time( rowTabulate(x) )

x<-NULL
```

Column and row-wise variances and standard deviations

Column and row-wise variances and standard deviations of a matrix

---

Description

Column and row-wise variances and standard deviations of a matrix

Usage

```
## S3 method for class 'matrix'
colVars(x, std = FALSE, na.rm = FALSE, parallel = FALSE)
## S3 method for class 'data.frame'
colVars(x, std = FALSE, na.rm = FALSE, parallel = FALSE)
colVars(x, std = FALSE, na.rm = FALSE, parallel = FALSE)
rowVars(x, std = FALSE, na.rm = FALSE, parallel = FALSE)
```

Arguments

x	A matrix with the data.
std	A boolean variable specyfying whether you want the variances (FALSE) or the standard deviations (TRUE) of each column.
na.rm	TRUE or FAlSE for remove NAs if exists.
parallel	Should parallel implentations take place in C++? The default value is FALSE.

Details

We found this on stackoverflow which was created by David Arenburg. We then modified the function to match the sums type formula of the variance, which is faster.

Value

A vector with the column variances or standard deviations.

Author(s)

Michail Tsagris and Manos Papadakis.

R implementation and documentation: Michail Tsagris <mtsagris@uoc.gr> and Manos Papadakis <papadakm95@gmail.com>.

```
x <- matrix( rnorm(100 * 100), ncol = 100 )
a2 <- colVars(x)
x<-a2<-NULL
```

`Column and rows-wise mean absolute deviations`

Column and row-wise mean absolute deviations

Description

Column and row-wise mean absolute deviations.

Usage

```
colMads(x,method = "median",na.rm=FALSE,parallel = FALSE)
rowMads(x,method = "median",na.rm=FALSE,parallel = FALSE)
```

Arguments

`x`	A matrix with the data.
`method`	A character vector with values "median", for median absolute deviation or "mean", for mean absolute deviation.
`na.rm`	A logical value TRUE/FALSE to remove NAs.
`parallel`	A boolean value for parallel version.

Details

The functions is written in C++ in order to be as fast as possible.

Value

A vector with the column-wise mean absolute deviations.

Author(s)

Michail Tsagris

R implementation and documentation: Michail Tsagris <mtsagris@uoc.gr> and Manos Papadakis <papadakm95@gmail.com>.

See Also

colMedians, rowMedians, colVars, colmeans, colMeans (buit-in R function)

Examples

x<-NULL
```

Column-row wise minima and maxima of two matrices

Column-row wise minima and maxima of two matrices

Description

Column-row wise minima and maxima of two matrices.

Usage

```
colPmax(x, y)
colPmin(x, y)
```

Arguments

x	A numerical vector with numbers.
y	A numerical vector with numbers.

Details

The parallel minima or maxima are returned. This are the same as the base functions pmax and pmin.

Value

A numerical vector/matrix with numbers, whose length is equal to the length of the inititals matrices containing the maximum or minimum between each pair.

Author(s)

Manos Papadakis

R implementation and documentation: Manos Papadakis <papadakm95@gmail.com>.

See Also

Sort, colMins, colMaxs, colMedians

Examples

```
x <- matrix(rnorm(100),10,10)
y <- matrix(rnorm(100),10,10)
res<-colPmax(x, y)
res<-colPmin(x, y)
x<-y<-NULL
```

`Column-wise differences`
Column-wise differences

Description

Column-wise differences.

Usage

```
coldiffs(x)
```

Arguments

x	A matrix with numbers.

Details

This function simply does this function x[, -1] - x[, -k], where k is the last column of the matrix x. But it does it a lot faster. That is, 2nd column - 1st column, 3rd column - 2nd column, and so on.

Value

A matrix with one column less containing the differences between the successive columns.

Author(s)

Manos Papadakis

R implementation and documentation: Manos Papadakis <papadakm95@gmail.com>.

See Also

x <- matrix( rnorm(50 * 10), ncol = 10 )
res<-coldiffs(x)

x<-NULL
```

Column-wise kurtosis and skewness coefficients
Column-wise kurtosis and skewness coefficients

Description

Column-wise kurtosis and skewness coefficients.

Usage

```
colkurtosis(x, pvalue = FALSE)

colskewness(x, pvalue = FALSE)
```

Arguments

x	A matrix with the data, where the rows denote the samples and the columns are the variables.
pvalue	If you want a hypothesis test that the skewness or kurtosis are significant set this to TRUE. This checks whether the skewness is significantly different from 0 and whether the kurtosis is significantly different from 3.

Details

The skewness and kurtosis coefficients are calculated. For the skewness coefficient we use the sample unbiased version of the standard deviation. For the kurtosis, we do not subtract 3.

Value

If "pvalue" is FALSE, a vector with the relevant coefficient. Otherwise a matrix with two columns. The kurtosis or skewness coefficient and the p-value from the hypothesis test that they are significantly different from 3 or 0 respectively.

Author(s)

Michail Tsagris

R implementation and documentation: Michail Tsagris <mtsagris@uoc.gr> and Manos Papadakis <papadakm95@gmail.com>.

skew, skew.test2, colMedians, colmeans, colVars, sftests

Examples

```
## 200 variables, hence 200 F-tests will be performed
x = matrix( rnorm(200 * 50), ncol = 50 )
## 200 observations in total
system.time( colkurtosis(x) )
system.time( colskewness(x) )
x <- NULL
```

Column-wise matching coefficients

Column-wise matching coefficients

Description

Column-wise matching coefficients.

Usage

```
match.coefs(x, y = NULL, ina, type = "jacc")
```

Arguments

x	A matrix with the data, where the rows denote the samples and the columns are the variables.
y	A second matrix with the data of the second group. If this is NULL (default value) then the argument ina must be supplied. Notice that when you supply the two matrices the procedure is two times faster.
ina	A numerical vector with 1s and 2s indicating the two groups. Be careful, the function is designed to accept only these two numbers. In addition, if your "y" is NULL, you must specify "ina".
type	This denotes the type of matching coefficient to calculate. For the Jaccard index put "jacc". For the simple matching coefficient put "smc" or else both of them will be calculated.

Details

Two matrices are given as imput and for each column matching coefficients are calculated, either the Jaccard or the simple matching coefficient or both.

Value

A matrix with one or two columns, depending on the type you have specified. If you specify "both", there will be two columns, if you specify "jacc" or "smc" then just one column.

Author(s)

Michail Tsagris

R implementation and documentation: Michail Tsagris <mtsagris@uoc.gr> and Manos Papadakis <papadakm95@gmail.com>.

a <- match.coefs(x, y, type = "both")
x <- NULL
y <- NULL
```

Column-wise minimum and maximum

Column-wise minimum and maximum of a matrix

Description

Column-wise minimum and maximum of a matrix.

Usage

```
colMins(x, value = FALSE, parallel = FALSE)

colMaxs(x, value = FALSE, parallel = FALSE)

colMinsMaxs(x)
```

Arguments

x	A numerical matrix with data.
value	If the value is FALSE it returns the indices of the minimum/maximum, otherwise it returns the minimum and maximum values.
parallel	Do you want to do it in parallel in C++? TRUE or FALSE. The parallel will return the minimum/maximum value only. It will never return the indices.

Value

A vector with the relevant values.

s2 <- apply(x, 2, min)

s1 <- colMaxs(x)
s2 <- apply(x, 2, max)

s1 <- colMinsMaxs(x)
s2 <- c(apply(x, 2, min), apply(x, 2, max))

x<-s1<-s2<-NULL
```

`Column-wise MLE of some univariate distributions`

Column-wise MLE of some univariate distributions

Description

Column-wise MLE of some univariate distributions.

Usage

```
colexpmle(x)
colexp2.mle(x)
colgammamle(x, tol = 1e-07)
colinvgauss.mle(x)
collaplace.mle(x)
collindley.mle(x)
colmaxboltz.mle(x)
colnormal.mle(x)
colpareto.mle(x)
colrayleigh.mle(x)
colvm.mle(x, tol = 1e-07)
colweibull.mle(x, tol = 1e-09, maxiters = 100, parallel = FALSE)
colnormlog.mle(x)
```

Arguments

x	A numerical matrix with data. Each column refers to a different vector of observations of the same distribution. For exponential, 2 parameter exponential, Weibull, gamma, inverse Gaussian, Maxwell-Boltzman, Lindley, Rayleigh and Pareto distributions, the numbers must be greater than zero. For the Poisson and geometric distributions, the numbers must be integers, 0, 1, 2,... For the Normal and Laplace distribution the numbers can take any value. The von Mises distribution takes values beween 0 and 2 * pi (radians).
tol	The tolerance value to terminate the Newton-Fisher algorithm.
maxiters	The maximum number of iterations to implement.
parallel	Do you want to calculations to take place in parallel? The default value is FALSE

Details

For each column, the same distribution is fitted and its parameter and log-likelihood are computed.

Value

A matrix with two, three or five (for the colnormlog.mle) columns. The first one or the first two contain the parameter(s) of the distribution and the other columns contain the log-likelihood values.

```

`Column-wise uniformity Watson test for circular data`
Column-wise uniformity tests for circular data

Description

Column-wise uniformity tests for circular data.

Usage

```
colwatsons(u)
```

Arguments

u	A numeric matrix containing the circular data which are expressed in radians. Each column is a different sample.

Details

These tests are used to test the hypothesis that the data come from a circular uniform distribution. The Kuiper test is much more time consuming and this is why it not implemented yet. Once we figure out a way to make it fast, we will incldue it.

Value

A matrix with two columns, the value of the test statistic and its associated p-value.

Author(s)

Michail Tsagris

R implementation and documentation: Michail Tsagris <mtsagris@uoc.gr>

References

x <- NULL
```

`Column-wise Yule's Y (coefficient of colligation)`
Column-wise Yule's Y (coefficient of colligation)

Description

Column-wise Yule's Y (coefficient of colligation).

Usage

```
col.yule(x, y = NULL, ina)
```

Arguments

x	A matrix with 0 and 1. Every column refers to a different sample or variable.
y	A second matrix, of the same dimensions as x, with 0 and 1. Every column refers to a different sample or variable.
ina	If y is NULL, ina must be specified. This is a numeric vector with 1s and 2s, indicating the group of each row.

Details

Yule's coefficient of colligation is calculated for every column.

Value

A vector with Yule's Y, one for every column of x is returned.

Author(s)

Michail Tsagris

R implementation and documentation: Michail Tsagris <mtsagris@uoc.gr>

```

Convert a dataframe to matrix

Convert a dataframe to matrix

Description

Convert a dataframe to matrix.

Usage

```
data.frame.to_matrix(x,col.names = NULL,row.names = NULL)
```

Arguments

x	A Numeric matrix with data and NAs.
col.names	A boolean value for keeping the colnames for argument x or a character vector for the new colnames.
row.names	A boolean value for keeping the rownames for argument x or a character vector for the new rownames.

Details

This functions converts a dataframe to matrix. Even if there are factors, the function converts them into numerical values. Attributes are not allowed for now.

Value

A matrix wich has the numrical values from the dataframe.

Author(s)

Manos Papadakis

R implementation and documentation: Manos Papadakis <papadakm95@gmail.com>

`Convert R function to the Rfast's coresponding`
Convert R function to the Rfast's coresponding

Description

Convert R function to the Rfast's coresponding.

Usage

```
as.Rfast.function(Rfunction.name,margin=NULL)
```

Arguments

`Rfunction.name`	An character value with the name of the function.
`margin`	A logical function for return the column-row wise function.

Details

Given the name of R function, it returns the coresponding function's name from Rfast.

Value

The coresponding Rfast function.

Author(s)

Manos Papadakis and Michail Tsagris

R implementation and documentation: Manos Papadakis <papadakm95@gmail.com> and Michail Tsagris <mtsagris@uoc.gr>.

Examples

```
res<-as.Rfast.function("var")
```

Correlation based forward regression
Correlation based forward regression.

Description

Correlation based forward regression.

Usage

```
cor.fsreg(y, x, ystand = TRUE, xstand = TRUE, threshold = 0.05,
tolb = 2, tolr = 0.02, stopping = "BIC")
```

Arguments

y	A numerical vector.
x	A matrix with data, the predictor variables.
ystand	If this is TRUE the response variable is centered. The mean is subtracted from every value.
xstand	If this is TRUE the independent variables are standardised.
threshold	The significance level, set to 0.05 by default. Bear in mind that the logarithm of it is used, as the logarithm of the p-values is calculated at every point. This will avoid numerical overflows and small p-values, less than the machine epsilon, being returned as zero.
tolb	If we see only the significane of the variables, many may enter the linear regression model. For this reason, we also use the BIC as a way to validate the inclusion of a candidate variable. If the BIC difference between two successive models is less than the tolerance value, the variable will not enter the model, even if it statistically significant. Set it to 0 if you do not want this extra check.
tolr	This is an alternative to the BIC change and it uses the adjusted coefficient of determination. If the increase in the adjusted R^2 is more than the tolr continue.
stopping	This refers to the type of extra checking to do. If you want the BIC check, set it to "BIC". If you want the adjusted R^2 check set this to "ar2". Or, if you want both of them to take place, both of these criteria to be satisfied make this "BICR2".

Details

The forward regression tries one by one the variables using the F-test, basically partial F-test every time for the latest variable. This is the same as testing the significance of the coefficient of this latest enetered variable. Alternatively the correlation can be used and this case the partial correlation coefficient. There is a direct relationship between the t-test statistic and the partial correlation coefficient. Now, instead of having to calculate the test statistic, we calculate the partial correlation coefficient. Using Fisher's z-transform we get the variance imediately. The partial correlation coefficient, using Fisher's z-transform, and the partial F-test (or the coefficient's t-test statistic) are not identical. They will be identical for large sample sizes though.

Value

A matrix with three columns, the index of the selected variables, the logged p-value and the the test statistic value and the BIC or adjusted R^2 of each model. In the case of stopping="BICR2" both of these criteria will be returned.

Examples

```
## 200 variables, hence 200 univariate regressions are to be fitted
x <- matrnorm(200,  100)
y <- rnorm(200)
system.time( cor.fsreg(y, x) )
x <- NULL
```

Correlation between pairs of variables

Correlation between pairs of variables

Description

Correlations between pairs of variables.

Usage

```
corpairs(x, y, rho = NULL, logged = FALSE, parallel = FALSE)
```

Arguments

x	A matrix with real valued data.
y	A matrix with real valued data whose dimensions match those of x.
rho	This can be a vector of assumed correlations (equal to the number of variables or the columns of x or y) to be tested. If this is not the case, leave it NULL and only the correlations will be returned.
logged	Should the p-values be returned (FALSE) or their logarithm (TRUE)? This is taken into account only if "rho" is a vector.
parallel	Should parallel implentations take place in C++? The default value is FALSE.

Details

The paired correlations are calculated. For each column of the matrices x and y the correlation between them is calculated.

Value

A vector of correlations in the case of "rho" being NULL, or a matrix with two extra columns, the test statistic and the (logged) p-value.

```

`Correlations` *Correlation between a vector and a set of variables*

Description

Correlation between a vector and a set of variables.

Usage

```
correls(y, x, type = "pearson", a = 0.05, rho = 0)
groupcorrels(y, x, type = "pearson", ina)
```

Arguments

`y`	A numerical vector.
`x`	A matrix with the data.
`type`	The type of correlation you want. "pearson" and "spearman" are the two supported types for the "correls" because their standard error is easily calculated. For the "groupcorrels" you can also put "kendall" because no hypothesis test is performed in that function.
`a`	The significance level used for the confidence intervals.
`rho`	The value of the hypothesised correlation to be used in the hypothesis testing.
`ina`	A factor variable or a numeric variable idicating the group of each observation.

Details

The functions uses the built-in function "cor" which is very fast and then includes confidence intervals and produces a p-value for the hypothesis test.

Value

For the "correls" a matrix with 5 column; the correlation, the p-value for the hypothesis test that each of them is eaqual to "rho", the test statistic and the $a/2%$ lower and upper confidence limits.

For the "groupcorrels" a matrix with rows equal to the number of groups and columns equal to the number of columns of x. The matrix contains the correlations only, no statistical hypothesis test is performed.

b <- correls(y, x)
ina <- rep(1:2, each = 30)
b2 <- groupcorrels(y, x, ina = ina)
x <- NULL
```

Covariance and correlation matrix

Fast covariance and correlation matrix calculation

Description

Fast covariance and correlation matrix calculation.

Usage

```
cova(x, center = FALSE, large = FALSE)

cora(x, large = FALSE)
```

Arguments

x	A matrix with data. It has to be matrix, if it is data.frame for example the function does not turn it into a matrix.
center	If you want to center the data prior to applying the cross product of the mateix set this equal to TRUE, otherwise leave it NULL.
large	If you have large matrices, with thousands of rows and or many tens or hundreds of columns set this equal to TRUE in order to use Rfast's Crossprod or Tcrossprod functions. These functions are twice or up to 3 times faster than the correpsonding built-in functions.

Details

The calculations take place faster than the built-in functions cor as the number of variables increases. This is true if the number of variables is high, say from 500 and above. The "cova" on the other hand is always faster. For the "cova" in specific, we have an option to center the data prior to the cross product. This can be more stable if you have many tens of thousands of rows due to numerical issues that can arise.

For the correlation matrix we took the code from here

https://stackoverflow.com/questions/18964837/fast-correlation-in-r-using-c-and-parallelization/18965892#18965892

Value

The covariance or the correlation matrix.

Cox confidence interval for the ratio of two Poisson variables

Cox confidence interval for the ratio of two Poisson variables

---

Description

Cox confidence interval for the ratio of two Poisson variables.

Usage

```
cox.poisrat(x, y, alpha = 0.05)
col.coxpoisrat(x, y, alpha = 0.05)
```

Arguments

`x`	A numeric vector or a matrix with count data.
`y`	A numeric vector or a matrix with count data.
`alpha`	The 1 - confidence level. The default value is 0.05.

Details

Cox confidence interval for the ratio of two Poisson means is calculated.

Value

For the cox.poisrat a vector with three elements, the ratio and the lower and upper confidence interval limits. For the col.coxpoisrat a matrix with three columns, the ratio and the lower and upper confidence interval limits.

```

`Cross-Validation for the k-NN algorithm`

Cross-Validation for the k-NN algorithm

Description

Cross-Validation for the k-NN algorithm.

Usage

```
knn.cv(folds = NULL, nfolds = 10, stratified = FALSE, seed = NULL, y, x, k,
dist.type = "euclidean", type = "C", method = "average", freq.option = 0,
pred.ret = FALSE, mem.eff = FALSE)
```

Arguments

folds	A list with the indices of the folds.
nfolds	The number of folds to be used. This is taken into consideration only if "folds" is NULL.

`stratified`	Do you want the folds to be selected using stratified random sampling? This preserves the analogy of the samples of each group. Make this TRUE if you wish, but only for the classification. If you have regression (type = "R"), do not put this to TRUE as it will cause problems or return wrong results.
`seed`	If NULL different folds will be created every time. Otherwise set your own seed.
`y`	A vector of data. The response variable, which can be either continuous or categorical (factor is acceptable).
`x`	A matrix with the available data, the predictor variables.
`k`	A vector with the possible numbers of nearest neighbours to be considered.
`dist.type`	The type of distance to be used, "euclidean" or "manhattan".
`type`	Do you want to do classification ("C") or regression ("R")?
`method`	If you do regression (type = "R"), then how should the predicted values be calculated? Choose among the average ("average"), median ("median") or the harmonic mean ("harmonic") of the closest neighbours.
`freq.option`	If classification (type = "C") and ties occur in the prediction, more than one class have the same number of k nearest neighbours, there are three strategies available. Option 0 selects the first most frequent encountered. Option 1 randomly selects the most frequent value, in the case that there are duplicates.
`pred.ret`	If you want the predicted values returned set this to TRUE.
`mem.eff`	Boolean value indicating a conservative or not use of memory. Lower usage of memory/Having this option on will lead to a slight decrease in execution speed and should ideally be on when the amount of memory in demand might be a concern.

Details

The concept behind k-NN is simple. Suppose we have a matrix with predictor variables and a vector with the response variable (numerical or categorical). When a new vector with observations (predictor variables) is available, its corresponding response value, numerical or categorical, is to be predicted. Instead of using a model, parametric or not, one can use this ad hoc algorithm.

The k smallest distances between the new predictor variables and the existing ones are calculated. In the case of regression, the average, median, or harmonic mean of the corresponding response values of these closest predictor values are calculated. In the case of classification, i.e. categorical response value, a voting rule is applied. The most frequent group (response value) is where the new observation is to be allocated.

This function does the cross-validation procedure to select the optimal k, the optimal number of nearest neighbours. The optimal in terms of some accuracy metric. For the classification it is the percentage of correct classification and for the regression the mean squared error.

Value

A list including:

`preds`	If pred.ret is TRUE the predicted values for each fold are returned as elements in a list.

`crit` A vector whose length is equal to the number of k and is the accuracy metric for each k.

freq.option = 0, pred.ret = FALSE, mem.eff = FALSE)
```

Cross-Validation for the k-NN algorithm using the arc cosinus distance

Cross-Validation for the k-NN algorithm using the arc cosinus distance

---

Description

Cross-Validation for the k-NN algorithm using the arc cosinus distance.

Usage

```
dirknn.cv(y, x, k = 5:10, type = "C", folds = NULL, nfolds = 10,
stratified = TRUE, seed = NULL, parallel = FALSE, pred.ret = FALSE)
```

Arguments

`y`	A vector of data. The response variable, which can be either continuous or categorical (factor is acceptable).
`x`	A matrix with the available data, the predictor variables.
`k`	A vector with the possible numbers of nearest neighbours to be considered.
`type`	If your response variable y is numerical data, then this should be "R" (regression) or "WR" for distance weighted based nearest neighbours. If y is in general categorical set this argument to "C" (classification) or to "WC" for distance weighted based nearest neighbours.
`folds`	A list with the indices of the folds.
`nfolds`	The number of folds to be used. This is taken into consideration only if "folds" is NULL.
`stratified`	Do you want the folds to be selected using stratified random sampling? This preserves the analogy of the samples of each group. Make this TRUE if you wish, but only for the classification. If you have regression (type = "R"), do not put this to TRUE as it will cause problems or return wrong results.
`seed`	If NULL different folds will be created every time. Otherwise set your own seed.
`parallel`	Do you want th ecalculations to take place in parallel? The default value is FALSE.
`pred.ret`	If you want the predicted values returned set this to TRUE.

Details

The concept behind k-NN is simple. Suppose we have a matrix with predictor variables and a vector with the response variable (numerical or categorical). When a new vector with observations (predictor variables) is available, its corresponding response value, numerical or categorical, is to be predicted. Instead of using a model, parametric or not, one can use this ad hoc algorithm.

The k smallest distances between the new predictor variables and the existing ones are calculated. In the case of regression, the average, median, or harmonic mean of the corresponding response values of these closest predictor values are calculated. In the case of classification, i.e. categorical response value, a voting rule is applied. The most frequent group (response value) is where the new observation is to be allocated.

This function does the cross-validation procedure to select the optimal k, the optimal number of nearest neighbours. The optimal in terms of some accuracy metric. For the classification it is the percentage of correct classification and for the regression the mean squared error.

Value

A list including:

`preds`	If pred.ret is TRUE the predicted values for each fold are returned as elements in a list.
`crit`	A vector whose length is equal to the number of k and is the accuracy metric for each k. For the classification case it is the percentage of correct classification. For the regression case the mean square of prediction error.

```

Deep copy *Deep copy*

Description

Deep copy.

Usage

```
env.copy(x,all.names=FALSE)
```

Arguments

x	An environment object.
all.names	An logical value (TRUE or FALSE). Copy all the hidden variables or not.

Details

Deep copy of the environment object.

Value

A copy of the first argument.

```

`Density of the multivariate normal and t distributions`

Density of the multivariate normal and t distributions

Description

Density of the multivariate normal and t distributions.

Usage

```
dmvnorm(x, mu, sigma, logged = FALSE)
dmvt(x, mu, sigma, nu, logged = FALSE)
```

Arguments

`x`	A numerical matrix with the data. The rows correspond to observations and the columns to variables.
`mu`	The mean vector.
`sigma`	The covariance matrix.
`nu`	The degrees of freedom for the multivariate t distribution.
`logged`	Should the logarithm of the density be returned (TRUE) or not (FALSE)?

Details

The (log) density of the multivariate normal distribution is calculated for given mean vector and covariance matrix.

Value

A numerical vector with the density values calculated at each vector (row of the matrix x).

a2 <- dmvt(x, mu, s, 1)
x <- NULL
```

Design Matrix *Design Matrix*

Description

Design Matrix.

Usage

```
design_matrix(x, ones = TRUE)
```

Arguments

x	A character vector or a factor type vector or a dataframe. Do not supply a numerical vector.
ones	A boolean variable specifying whether to include the ones in the design matrix or not. The default value is TRUE.

Details

This function implements the R's "model.matrix" function and is used only when the x is a factor/charactervector or Dataframe.

Value

Returns the same matrix with model.matrix.

Author(s)

Manos Papadakis

R implementation and documentation: Manos Papadakis <papadakm95@gmail.com>

See Also

`model.matrix`

Examples

```
a <- design_matrix( iris[, 5] )
b <- model.matrix( ~ iris[,5] )  ## R's built-in function
all.equal(as.vector(a),as.vector(b)) ## true

a<-b<-NULL
```

Diagonal Matrix *Diagonal Matrix*

Description

Fill the diagonal of a matrix or create a diagonal and initialize it with a specific value.

Usage

```
Diag.fill(x,v=0)
Diag.matrix(len,v=0)
```

Arguments

x	A matrix with data.
len	Number of columns or rows.
v	Value or vector to initialize the diagonal of a matrix.By default "v=0".

Value

Diag.fill returns a diagonal matrix where all the elements in the diagonal are equal to "v".

Diag.matrix returns a diagonal matrix where has dimension "len,len" and all the elements in the diagonal are equal to "v". It is fast for huge matrices with dimensions more than [row,col] = [500,500]

f<-x<-NULL
```

Distance between vectors and a matrix

Distance between vectors and a matrix

Description

Distance between vectors and a matrix.

Usage

```
dista(xnew, x, type = "euclidean", k = 0, index = FALSE, trans = TRUE, square = FALSE)
```

Arguments

xnew	A matrix with some data or a vector.
x	A matrix with the data, where rows denotes observations (vectors) and the columns contain the variables.
type	This can be either "euclidean" or "manhattan".
k	Should the k smaller distances or their indices be returned? If k > 0 this will happen.
index	In case k is greater than 0, you have the option to get the indices of the k smallest distances.
trans	Do you want the returned matrix to be transposed? TRUE or FALSE.
square	If you choose "euclidean" as the method, then you can have the optino to return the squared Euclidean distances by setting this argument to TRUE.

Details

The target of this function is to calculate the distances between xnew and x without having to calculate the whole distance matrix of xnew and x. The latter does extra calculations, which can be avoided.

Value

A matrix with the distances of each xnew from each vector of x. The number of rows of the xnew and and the number of columns of xnew are the dimensions of this matrix.

Author(s)

Michail Tsagris.

R implementation and documentation: Michail Tsagris <mtsagris@uoc.gr> and Manos Papadakis <papadakm95@gmail.com>.

system.time( as.matrix( dist( rbind(xnew, x) ) ) )

x<-b<-a<-xnew<-NULL
```

`Distance correlation` *Distance correlation*

Description

Distance correlation.

Usage

```
dcor(x, y)
bcdcor(x, y)
```

Arguments

x	A numerical matrix.
y	A numerical matrix.

Details

The distance correlation or the bias corrected distance correlation of two matrices is calculated. The latter one is used for the hypothesis test that the distance correlation is zero (see dcor.ttest).

Value

The value of the distance correlation of the bias corrected distance correlation.

Author(s)

Manos Papadakis

R implementation and documentation: Michail Tsagris <mtsagris@uoc.gr> and Manos Papadakis <papadakm95@gmail.com>.

res<-bcdcor(x, y)

x<-y<-NULL
```

Distance matrix *Distance matrix*

Description

Distance matrix.

Usage

```
Dist(x, method = "euclidean", square = FALSE, p = 0,vector = FALSE)
vecdist(x)
```

Arguments

x	A matrix with data. The distances will be calculated between pairs of rows. In the case of **vecdist** this is a vector. For the haversine distance it must be a matrix with two columns, the first column is the latitude and the second the longitude.
method	This is either "euclidean", "manhattan", "canberra1", "canberra2", "minimum", "maximum", "minkowski", "bhattacharyya", "hellinger", "kullback_leibler", "jensen_shannon" or "haversine".
square	If you choose "euclidean" or "hellinger" as the method, then you can have the option to return the squared Euclidean distances by setting this argument to TRUE.
p	This is for the the Minkowski, the power of the metric.
vector	For return a vector instead a matrix.

Details

The distance matrix is computer with an extra argument for the Euclidean distances. The "kullback_leibler" refers to the symmetric Kullback-Leibler divergence.

Value

A square matrix with the pairwise distances.

Author(s)

Manos Papadakis.

R implementation and documentation: Manos Papadakis <papadakm95@gmail.com>.

```

Distance variance and covariance

Distance variance and covariance

Description

Distance variance and covariances.

Usage

```
dvar(x)
dcov(x, y)
```

Arguments

x	A numerical matrix or a vector.
y	A numerical matrix or a vector.

Details

The distance variance of a matrix/vector or the distance covariance of two matrices is calculated. For the distance variance of a vector we use the fast method of Huo and Szekely (2016).

Value

The distance covariance or distance variance.

Author(s)

Manos Papadakis

`Eigenvalues and eigenvectors in high dimensional principal component analysis`

Eigenvalues in high dimensional principal component analysis

Description

Eigenvalues in high dimensional (n«p) principal component analysis.

Usage

```
hd.eigen(x, center = TRUE, scale = FALSE, k = NULL, vectors = FALSE, large = FALSE)
```

Arguments

`x`	A numerical $n \times p$ matrix with data where the rows are the observations and the columns are the variables.
`center`	Do you want your data centered? TRUE or FALSE.
`scale`	Do you want each of your variables scaled, i.e. to have unit variance? TRUE or FALSE.
`k`	If you want a specific number of eigenvalues and eigenvectors set it here, otherwise all eigenvalues (and eigenvectors if requested) will be returned.
`vectors`	Do you want the eigenvectors be returned? By dafault this is FALSE.
`large`	If you have large matrices, with thousands of rows and or many tens or hundreds of columns set this equal to TRUE in order to use Rfast's `Crossprod` or `Tcrossprod` functions. These functions are twice or up to 3 times faster than the correpsonding built-in functions.

Details

When $n << p$, at most the first n eigenvalues are non zero. Hence, there is no need to calculate the other p-n zero eigenvalues. When center is TRUE, the eigenvalues of the covariance matrix are calculated. When both the center and scale is TRUE the eigenvalues of the correlation matrix are calculated. One or more eigenvectors (towards the end) will be 0. In general the signs might be the opposite than R's, but this makes no difference. We use the `Crossprod` instead of the relevant built-in function. The higher the dimensions of the matrix are the faster this function becomes.

Value

A list including:

values	A vector with the n (or first k) eigenvalues. The divisor in the crossproduc matrix is n-1 and not n.
vectors	A matrix of $p \times n$ or $p \times k$ eigenvectors.

```

Empirical and exponential empirical likelihood tests for one sample

Empirical and exponential empirical likelihood tests for one sample

---

Description

Empirical and exponential empirical likelihood tests for one sample.

Usage

```
eel.test1(x, mu, tol = 1e-09, logged = FALSE)
el.test1(x, mu, tol = 1e-07, logged = FALSE)
```

Arguments

x	A numerical vector.
mu	The hypothesised mean value.
tol	The tolerance value to stop the iterations of the Newton-Raphson.
logged	Should the logarithm of the p-value be returned? TRUE or FALSE.

Details

Exponential empirical likelihood is a non parametric method. In this case we use it as the non parametric alternative to the t-test. Newton-Raphson is used to maximise the log-likelihood ratio test statistic. In the case of no solution, NULL is returned. Despite the function having beeen written in R, it is pretty fast. As for the empirical likelihood ratio test, there is a condition for the range of possible values of mu. If mu is outside this range it is rejected immediately.

Value

`iters`	The number of iterations required by the Newton-Raphson algorithm. If no covnergence occured this is NULL. This is not returned for the empircial likelihood ratio test.
`info`	A vector with three elements, the value of the λ, the likelihood ratio test statistic and the relevant p-value. If no convergence occured, the value of the λ before is becomes NA, the value of test statistic is 10^5 and the p-value is 0. No convergence can be interpreted as rejection of the hypothesis test.
`p`	The estimated probabilities, one for each observation. If no covnergence occured this is NULL.

`Empirical and exponential empirical likelihood tests for two samples`

Empirical and exponential empirical likelihood tests for two samples

---

Description

Empirical and exponential empirical likelihood tests for two samples.

Usage

```
eel.test2(x, y, tol = 1e-09, logged = FALSE)
el.test2(x, y, tol = 1e-07, logged = FALSE)
```

Arguments

x	A numerical vector.
y	Another numerical vector.
tol	The tolerance value to stop the iterations of the Newton-Raphson.
logged	Should the logarithm of the p-value be returned? TRUE or FALSE.

Details

Empirical and exponential empirical likelihood are two non parametric hypothesis testing methods. We can use them as non parametric alternatives to the t-test. Newton-Raphson is used to maximise the log-likelihood ratio test statistic. In the case of no solution, NULL is returned.

Value

iters	The number of iterations required by the Newton-Raphson algorithm. If no covnergence occured this is NULL.
info	A vector with three elements, the value of the λ, the likelihood ratio test statistic and the relevant p-value. If no convergence occured, the value of the λ before is becomes NA, the value of test statistic is 10^5 and the p-value is 0. No convergence can be interpreted as rejection of the hypothesis test.
p1	The estimated probabilities, one for each observation for the first sample. If no covnergence occured this is NULL.
p2	The estimated probabilities, one for each observation for the second sample. If no covnergence occured this is NULL.

`Energy distance between matrices`

Energy distance between matrices

Description

Energy distance between matrices.

Usage

```
edist(x, y=NULL)
```

Arguments

x	A matrix with numbers or a list with matrices.
y	A second matrix with data. The number of columns of x and y must match. The number of rows can be different.

Details

This calculates the energy distance between two matrices. It will work even for tens of thousands of rows, it will just take some time. See the references for more information. If you have many matrices and want to calculate the distance matrix, then put them in a list and use the function.

Value

If "x" is matrix, a numerical value, the energy distance. If "x" is list, a matrix with all pairwsie distances of the matrices.

Equality of objects *Equality of objects*

Description

Equality of objects.

Usage

```
all_equals(x,y,round_digits = FALSE,without_attr=FALSE,fast_result=FALSE)
```

Arguments

x	A Matrix, List, Dataframe or Vector.
y	A Matrix, List, Dataframe or Vector.
round_digits	The digit for rounding numbers.
without_attr	A boolean value (TRUE/FALSE) for deleting attributes. Be carefull although because some atributes are very important for you item.
fast_result	A boolean value (TRUE/FALSE) for using just identical.But you can combine only with round_digits argument.

Value

A boolean (TRUE/FALSE) value which represents if the items x and y are equal.

`Estimation of an AR(1) model`

Estimation of an AR(1) model

Description

Estimation of an AR(1) model.

Usage

```
ar1(y, method = "cmle")
colar1(y, method = "cmle")
```

Arguments

`y`	For the case of **ar1** this is a vector of time series. For the case of **colar1** this is a matrix where weach column represents a time series.
`method`	This can be either "cmle" for conditional maximum likelihood or "yw" for the Yule-Walker equations.

Details

Instead of the classical MLE for the AR(1) model which requires numerical optimsation (Newton-Raphson for example) we estimate the parameters of the AR(1) model using conditional maximum likelihood. This procedure is described in Chapter 17 in Lee (2006). In some, it assumes that the first observation is deterministic and hence conditioning on that observation, there is a closed form solution for the parameters. The second alternative is to use the method of moments and hence the Yule-Walker equations.

Value

`param`	For the case of **ar1** this is a vector with three elements, the constant term, the ϕ term (lag coefficient) and the variance. For the case of **colar1** this is a matrix with three columns, eahc of which carries the same aforementioned elements.

Estimation of the Box-Cox transformation

Estimation of the Box-Cox transformation

Description

Estimation of the Box-Cox transformation.

Usage

```
bc(x, low = -1, up = 1)
```

Arguments

x	A numerical vector with strictly positive values.
low	The lowest value to search for the best λ parameter.
up	The highest value to search for the best λ parameter.

Details

The functions estimates the best λ in the Box-Cox power transformation.

Value

The optimal value of λ.

Exact t-test for 2 independent samples

Exact t-test for 2 independent samples

Description

Exact t-test for 2 independent samples.

Usage

```
exact.ttest2(x, y)
```

Arguments

x	A numerical vector with the data.
y	A numerical vector with the data.

Details

This function performs an exact t-test. With few observations, permutation or bootstrap calculation of the p-value is advisable. However, with even fewer observations, one can perform all possible permutations and calculate the exact p-value. This is what this function does. BUT, pay attention, as this works with few samples. If for example each sample contains 15 numbers, you will need a lot of memory (more than 17 GB) for this function to work. the reason is that we create the matrix with all possible permutations first and then perform the two-sample t-test.

Value

A vector with the number of permutations, test statistic and the permutation based p-value.

`Exponential empirical likelihood for a one sample mean vector hypothesis testing`

Exponential empirical likelihood for a one sample mean vector hypothesis testing

---

Description

Exponential empirical likelihood for a one sample mean vector hypothesis testing.

Usage

```
mv.eeltest1(x, mu, tol = 1e-06)
```

Arguments

`x`	A matrix containing Euclidean data.
`mu`	The hypothesized mean vector.
`tol`	The tolerance value used to stop the Newton-Raphson algorithm.

Details

Multivariate hypothesis test for a one sample mean vector. This is a non parametric test and it works for univariate and multivariate data. The p-value is currently computed only asymptotically (no bootstrap calibration at the moment).

Value

A list including:

`p`	The estimated probabiities.
`lambda`	The value of the Lagrangian parameter λ.
`iters`	The number of iterations required by the newton-Raphson algorithm.
`info`	The value of the log-likelihood ratio test statistic along with its corresponding p-value.

```

`Exponential empirical likelihood hypothesis testing for two mean vectors`

Exponential empirical likelihood hypothesis testing for two mean vectors

---

Description

Exponential empirical likelihood hypothesis testing for two mean vectors.

Usage

```
mv.eeltest2(y1, y2, tol = 1e-07, R = 0)
```

Arguments

y1	A matrix containing the Euclidean data of the first group.
y2	A matrix containing the Euclidean data of the second group.
tol	The tolerance level used to terminate the Newton-Raphson algorithm.
R	If R is 0, the classical chi-sqaure distribution is used, if R = 1, the corrected chi-square distribution (James, 1954) is used and if R = 2, the modified F distribution (Krishnamoorthy and Yanping, 2006) is used.

Details

Exponential empirical likelihood is a non parametric hypothesis testing procedure for one sample. The generalisation to two (or more samples) is via searching for the mean vector that minimises the sum of the two test statistics.

Value

A list including:

test	The empirical likelihood test statistic value.
modif.test	The modified test statistic, either via the chi-square or the F distribution.
pvalue	The p-value.
iters	The number of iterations required by the newton-Raphson algorithm.
mu	The estimated common mean vector.

Fast and general - untyped represantation of a factor variable

Fast and general represantation of a factor variable

Description

Fast and general represantation of a factor variable.

Usage

```
ufactor(x)
## S3 method for class 'ufactor'
x[i]
## S3 method for class 'ufactor'
print(x,...)
```

Arguments

x	A vector with data.
i	An integer value/vector which is the index/indices to the element you want to access.
...	Anything the user want.

Details

This is a general implementation of factor structure. For access the fields of a "ufactor" use the "$" operator.

Value

An object of class "ufactor". This object holds 2 fields:

levels: the levels of the variable in his initial type values: the values of the variable in his initial type

Author(s)

Manos Papadakis

R implementation and documentation: and Manos Papadakis <papadakm95@gmail.com>.

```

FBED variable selection method using the correlation

FBED variable selection method using the correlation

Description

FBED variable selection method using the correlation.

Usage

```
cor.fbed(y, x, ystand = TRUE, xstand = TRUE, alpha = 0.05, K = 0)
```

Arguments

y	The response variable, a numeric vector.
x	A matrix with the data, where the rows denote the samples and the columns are the variables.
ystand	If this is TRUE the response variable is centered. The mean is subtracted from every value.
xstand	If this is TRUE the independent variables are standardised.
alpha	The significance level, set to 0.05 by default.
K	The number of times to repeat the process. The default value is 0.

Details

FBED stands for Forward Backward with Earcly Dropping. It is a variation of the classical forward selection, where at each step, only the statistically significant variables carry on. The rest are dropped. The process stops when no other variables can be selected. If K = 1, the process is repeated testing sequentially again all those that have not been selected. If K > 1, then this is repeated.

In the end, the backward selection is performed to remove any falsely included variables. This backward phase has not been implemented yet.

Value

A list including:

`runtime`	The duration of the process.
`res`	A matrix with the index of the selected variable, their test statistic value and the associated p-value.
`info`	A matrix with two columns. The cumulative number of variables selected and the number of tests for each value of K.

`Find element` *Find element*

Description

Search a value in an unordered vector.

Usage

```
is_element(x, key)
```

Arguments

`x`	A vector or matrix with the data.
`key`	A value to check if exists in the vector x.

Details

Find if the key exists in the vector and return returns TRUE/FALSE if the value is been found. If the vector is unordered it is fast but if the vector is ordered then use binary_search. The functions is written in C++ in order to be as fast as possible.

Value

TRUE/FALSE if the value is been found.

Author(s)

Manos Papadakis

R implementation and documentation: Manos Papadakis <papadakm95@gmail.com>.

`Fitted probabilities of the Terry-Bradley model`

Fitted probabilities of the Terry-Bradley model

Description

Fitted probabilities of the Terry-Bradley model.

Usage

```
btmprobs(x, tol = 1e-09)
```

Arguments

`x`	A numerical square, usually not symmetric, matrix with discrete valued data. Each entry is a frequency, to give an example, the number of wins. x[i, j] is the number of wins of home team i against guest team j. x[j, i] is the number of wins of home team j against guest team i.
`tol`	The tolerance level to terminate the iterative algorithm.

Details

It fits a Bradley-Terry model to the given matrix and returns the fitted probabilities only.

Value

A list including:

`iters`	The numbetr of iterations required.
`probs`	A vector with probabilities which sum to 1. This is the probability of win for each item (or team in our hypothetical example).

`Fitting a Dirichlet distribution via Newton-Rapshon`

Fitting a Dirichlet distribution via Newton-Rapshon

Description

Fitting a Dirichlet distribution via Newton-Rapshon.

Usage

```
diri.nr2(x, type = 1, tol = 1e-07)
```

Arguments

x	A matrix containing the compositional data. Zeros are not allowed.
type	Type 1 uses a vectorised version of the Newton-Raphson (Minka, 2012). In high dimensions this is to be preferred. If the data are too concentrated, regardless of the dimensions, this is also to be preferrred. Type 2 uses the regular Newton-Raphson, with matrix multiplications. In small dimensions this can be considerably faster.
tol	The tolerance level idicating no further increase in the log-likelihood.

Details

Maximum likelihood estimation of the parameters of a Dirichlet distribution is performed via Newton-Raphson. Initial values suggested by Minka (2012) are used.

Value

A list including:

`loglik`	The value of the log-likelihood.
`param`	The estimated parameters.

```

Floyd-Warshall algorithm

Floyd-Warshall algorithm for shortest paths in a directed graph

---

Description

Floyd-Warshall algorithm for shortest paths in a directed graph.

Usage

```
floyd(x)
```

Arguments

x	The adjacency matrix of a directed graph. A positive number (including) in x[i, j] indicates that there is an arrow from i to j and it also shows the cost of going from i to j. Hence, the algorithm will find not only the shortest path but also the with the smallest cost. A value of NA means that there is no path. Put positive number only, as negative will cause problems.

Details

The Floyd-Warshall algorithm is designed to find the shortest path (if it exists) between two nodes in a graph.

Value

A matrix, say z, with 0 and positive numbers. The elements denote the length of the shortest path between each pair of points. If z[i, j] is zero it means that there is no cost from i to j. If z[i, j] has a positive value it means that the length of going from i to j is equal to that value.

`Forward selection with generalised linear regression models`
Variable selection in generalised linear regression models with forward selection

Description

Variable selection in generalised linear regression models with forward selection

Usage

```
fs.reg(y, ds, sig = 0.05, tol = 2, type = "logistic")
```

Arguments

`y`	The dependent variable. This can either be a binary numeric (0, 1) or a vector with integers (numeric or integer class), count data. The first case is for the binary logistic regression and the second for the Poisson regression.
`ds`	The dataset; provide a matrix where columns denote the variables and the rows the observations. The variables must be continuous, no categorical variables are accepted.
`sig`	Significance level for assessing the p-values significance. Default value is 0.05.
`tol`	The difference bewtween two successive values of the stopping rule. By default this is is set to 2. If for example, the BIC difference between two succesive models is less than 2, the process stops and the last variable, even though significant does not enter the model.
`type`	If you have a binary dependent variable, put "logistic" or "quasibinomial". If you have percentages, values between 0 and 1, including 0 and or 1, use "quasibinomial" as well. If you have count data put "poisson".

Details

The classical forward regression is implemented. The difference is that we have an extra step of check. Even if a variable is significant, the BIC of the model (with that variable) is calculated. If the decrease from the previous BIC (of the model without this variable) is less thatn a prespecified by the user value (default is 2) the variable wil enter. This way, we guard somehow against over-fitting.

Value

A matrix with for columns, the selected variables, the logarithm of their p-value, their test statistic and the BIC of the model with these variables included. If no variable is selected, the matrix is empty.

```
set.seed(123)

#simulate a dataset with continuous data
x <- matrnorm(100, 50)
y <- rpois(100, 10)
a <- fs.reg(y, x, sig = 0.05, tol = 2, type = "poisson")
x <- NULL
```

G-square and Chi-square test of conditional indepdence

G-square test of conditional indepdence

Description

G-square test of conditional indepdence with and without permutations.

Usage

```
g2Test(data, x, y, cs, dc)
g2Test_perm(data, x, y, cs, dc, nperm)
chi2Test(data, x, y, cs, dc)
```

Arguments

data	A numerical matrix with the data. **The minimum must be 0, otherwise the function can crash or will produce wrong results**. The data must be consecutive numbers.
x	A number between 1 and the number of columns of data. This indicates which variable to take.
y	A number between 1 and the number of columns of data (other than x). This indicates the other variable whose independence with x is to be tested.
cs	A vector with the indices of the variables to condition upon. It must be non zero and between 1 and the number of variables. If you want unconditional independence test see g2Test_univariate and g2Test_univariate_perm. If there is an overlap between x, y and cs you will get 0 as the value of the test statistic.

dc — A numerical value equal to the number of variables (or columns of the data matrix) indicating the number of distinct, unique values (or levels) of each variable. Make sure you give the correct numbers here, otherwise the degrees of freedom will be wrong.

nperm — The number of permutations. The permutations test is slower than without permutations and should be used with small sample sizes or when the contigency tables have zeros. When there are few variables, R's "chisq.test" function is faster, but as the number of variables increase the time difference with R's procedure becomes larger and larger.

Details

The functions calculates the test statistic of the G^2 test of conditional independence between x and y conditional on a set of variable(s) cs.

Value

A list including:

statistic — The G^2 or chi^2 test statistic.

df — The degrees of freedom of the test statistic.

x — The row or variable of the data.

y — The column or variable of the data.

Author(s)

Giorgos Borboudakis. The permutation version used a C++ code by John Burkardt.

R implementation and documentation: Manos Papadakis <papadakm95@gmail.com>.

```

Gamma regression with a log-link
Gamma regression with a log-link

Description

Gamma regression with a log-link.

Usage

```
gammareg(y, x, tol = 1e-07, maxiters = 100)
gammacon(y, tol = 1e-08, maxiters =50)
```

Arguments

y	The dependent variable, a numerical variable with non negative numbers.
x	A matrix or data.frame with the indendent variables.
tol	The tolerance value to terminate the Newton-Raphson algorithm.
maxiters	The maximum number of iterations that can take place in the regression.

Details

The gamma.reg fits a Gamma regression with a log-link. The gamma.con fits a Gamma regression with a log link with the intercept only (glm(y ~ 1, Gamma(log))).

Value

A list including:

deviance	The deviance value.
phi	The dispersion parameter (ϕ) of the regression. This is necessary if you want to perform an F hypothesis test for the significance of one or more independent variables.
be	The regression coefficient(s).
info	The number of iterations, the deviance and the dispersion parameter.

```

`Gaussian regression with a log-link`

Gaussian regression with a log-link

Description

Gaussian regression with a log-link.

Usage

```
normlog.reg(y, x, tol = 1e-07, maxiters = 100)
```

Arguments

`y`	The dependent variable, a numerical variable with non negative numbers.
`x`	A matrix or data.frame with the indendent variables.
`tol`	The tolerance value to terminate the Newton-Raphson algorithm.
`maxiters`	The maximum number of iterations that can take place in the regression.

Details

A Gaussian regression with a log-link is fitted.

Value

A list including:

i	The number of iterations required by the Newton-Raphson
loglik	The log-likelihood value.
deviance	The deviance value.
be	The regression coefficients

Generates random values from a normal and puts them in a matrix

Generates random values from a normal and puts them in a matrix

---

Description

Generates random values from a normal and puts them in a matrix.

Usage

```
matrnorm(n, p, seed = NULL)
```

Arguments

n	The sample size, the number of rows the matrix will have.
p	The dimensionality of the data, the nubmer of columns of the matrix.
seed	If you want the same to be generated again use a seed for the generator, an integer number.

Details

How many times did you have to simulated data from a (standard) normal distribution in order to test something? For example, in order to see the speed of `logistic_only`, one needs to generate a matrix with predictor variables. The same is true for other similar functions. In `sftests`, one would like to examine the typer I error of this test under the null hypothesis.

By using the Ziggurat method of generating standard normal variates, this function is really fast when you want to generate big matrices.

Value

An n x p matrix with data simulated from a standard normal distribution.

Get specific columns/rows fo a matrix

Get specific columns/rows fo a matrix

Description

Get specific columns/rows of a matrix.

Usage

```
columns(x,indices)
rows(x,indices)
```

Arguments

`x`	A matrix with data.
`indices`	An integer vector with the indices.

Value

A matrix with the specific columns/rows of argumment indices.

all.equal(x[indices,],rows(x,indices))

x<-indices<-NULL
```

Hash - Pair function *Hash - Pair function*

Description

Hash - Pair function.

Usage

```
hash.list(key,x)
```

Arguments

key	The keys of the given values.
x	The values.

Details

This function pairs each item of of key and value make a unique hash table.

Value

Returns the hash-list table.

Author(s)

Manos Papadakis

R implementation and documentation: Manos Papadakis <papadakm95@gmail.com>

See Also

hash.find

Examples

```
x <- hash.list(letters,c(1:26))
x[["a"]]==1
```

`Hash object` *Hash object*

Description

Hash object.

Usage

```
Hash(keys=NULL,values=NULL)
Hash.key.multi(x,...,sep = " ")
## S3 replacement method for class 'Hash'
x[...,sep = " "] <- value
## S3 method for class 'Hash'
x[...,sep = " "]
## S3 method for class 'Hash'
print(x,...)
## S3 method for class 'Hash'
length(x)
```

Arguments

`x`	A Hash object, using Hash function.
`values`	A vector with the values you want to store.
`value`	The values you want to store.
`keys`	A vector with keys for each values.
`sep`	A character value using to separate the multiple keys for each value.
`...`	One or more values for access or find elements.

Details

If you want to delete a key just insert the global variable "Rfast:::delete".

Hash: Create Hash object where every key has a value. Specify the type from the beggining (for speed). Use the argument "type" with one of the values "new.env, logical, character, integer, numeric". Hash.key.multi: search if key exists. If the keys are multiple, then use the argument "substr" to search inside each multiple for the specific key.

Value

A Hash object.

Author(s)

Manos Papadakis

R implementation and documentation: Manos Papadakis <papadakm95@gmail.com>.

Examples

```
x <- Hash(rnorm(10),sample(1:10))

x[1,2,13] <- 0.1234 # insert value using multi key. the same as x["1 2 13"] <- 0.1234
x[1,2,3] <- 15 # insert value using multi key. the same as x["1 2 3"] <- 15

Hash.key.multi(x,"1")
x # print Hash object using S3 generic
#x[1,2,3] <- Rfast:::delete # delete multi key. the same as x["1 2 3"] <- NULL
length(x)
```

Hash object to a list object

Hash object to a list object

Description

Hash object to a list object.

Usage

```
hash2list(x, sorting = FALSE)
```

Arguments

x	A hash table with two parts, the keys (number(s) as string) and the key values (a single number).
sorting	This is if you you want the numbers in the keys sorted. The default value is FALSE.

Details

For every key, there is a key value. This function creates a list and puts every pair of keys and value in a component of a list.

Value

A list whose length is equal to the size of the hash table.

```

`High dimensional MCD based detection of outliers`

High dimensional MCD based detection of outliers

Description

High dimensional MCD based detection of outliers.

Usage

```
rmdp(y, alpha = 0.05, itertime = 100)
```

Arguments

`y`	A matrix with numerical data with more columns (p) than rows (n), i.e. n<p.
`alpha`	The significance level, i.e. used to decide whether an observation is said to be considered a possible outlier. The default value is 0.05.
`itertime`	The number of iterations the algorithm will be ran. The higher the sample size, the larger this number must be. With 50 observations in R^1000 maybe this has to be 1000 in order to produce stable results.

Details

High dimensional outliers (n«p) are detected using a properly constructed MCD. The variances of the variables are used and the determinant is simply their product.

Value

A list including: runtime = runtime, dis = dis, wei = wei

`runtime`	The duration of the process.
`dis`	The final estimated Mahalanobis type normalised distances.
`wei`	A bollean variable vector specifying whether an observation is "clean" (TRUE) or a possible outlier (FALSE).
`cova`	The estimated covatriance matrix.

```

`Hypothesis test for the distance correlation`

Hypothesis test for the distance correlation

Description

Hypothesis test for the distance correlation.

Usage

```
dcor.ttest(x, y, logged = FALSE)
```

Arguments

x	A numerical matrix.
y	A numerical matrix.
logged	Do you want the logarithm of the p-value to be returned? If yes, set this to TRUE.

Details

The bias corrected distance correlation is used. The hypothesis test is whether the two matrices are independent or not. Note, that this test is size correct as both the sample size and the dimensionality goes to infinity. It will not have the correct type I error for univariate data or for matrices with just a couple of variables.

Value

A vector with 4 elements, the bias corrected distance correlation, the degrees of freedom, the test statistic and its associated p-value.

Hypothesis test for two means of percentages

Hypothesis test for two means of percentages

Description

Hypothesis test for two means of percentages.

Usage

```
percent.ttest(x, y, logged = FALSE)
```

Arguments

x	A numerical vector with the percentages of the first sample. Any value between 0 and 1 (inclusive) is allowed.
y	A numerical vector with the percentages of the first sample. Any value between 0 and 1 (inclusive) is allowed.
logged	Should the p-values be returned (FALSE) or their logarithm (TRUE)?

Details

This is the prop.reg but with a single categorical predictor which has two levels only. It is like a t-test for the means of two samples haivng percentages.

Value

A vector with three elements, the phi parameter, the test statistic and its associated p-value.

`Hypothesis test for von Mises-Fisher distribution over Kent distribution`
Hypothesis test for von Mises-Fisher distribution over Kent distribution

---

Description

The null hypothesis is whether a von Mises-Fisher distribution fits the data well, and the altenrative is that the Kent distribution is more suitable.

Usage

```
fish.kent(x, logged = FALSE)
```

Arguments

`x`	A numeric matrix containing the data as unit vectors in Euclidean coordinates.
`logged`	If you want the logarithm of the p-value ot be returned set this to TRUE.

Details

Essentially it is a test of rotational symmetry, whether Kent's ovalness parameter (beta) is equal to zero. This works for spherical data only.

Value

A vector with two elements, the value of the test statistic and its associated p-value.

Author(s)

Michail Tsagris

R implementation and documentation: Michail Tsagris <mtsagris@uoc.gr>

res<-kurt.test2(x, y)
```

`Index of the columns of a data.frame which are a specific type`

Index of the columns of a data.frame which are a specific type

---

Description

Index of the columns of a data.frame which are a specific type.

Usage

```
which.is(x,method="factor")
```

Arguments

`x`	A data.frame where some columns are expected to be factor variables.
`method`	A character value about the type. One of, "numeric","factor","integer","logical".

Details

The function is written in C++ and this is why it is very fast.

Value

A vector with the column indices which are factor variables. If there are no factor variables it will return an empty vector.

Insert/remove function names in/from the NAMESPACE file
Insert/remove function names in/from the NAMESPACE file

Description

Insert/remove function names in/from the NAMESPACE file.

Usage

```
AddToNamespace(path.namespace,path.rfolder)
RemoveFromNamespace(path.namespace,files.to.remove)
```

Arguments

`path.namespace`	An full path to the NAMESPACE file.
`path.rfolder`	An full path to the directory the new files to be added are stored.
`files.to.remove`	An character with the names of the functions to be removed from file NAMESPACE.

Details

AddToNameSpace: Reads the files that are exported in NAMESPACE and the functions that are inside rfolder (where R files are) and insert every function that is not exported. For that you must add the attribute "#[export]" above every function you wish to export. Also you can use the attribute "#[export s3]" for exporting S3methods. Finally, if you don't want the program to read a file just add at the top of the file the attribute "#[dont read]".

RemoveFromNamespace: Remove every function, from argument "files.to.remove", from NAMESPACE.

Value

AddToNameSpace:

`without export`	A character vector with the names of the R functions that don't have te "#[export]" attribute.
`hidden functions`	A character vector with the names of the R functions that are hidden.

RemoveFromNamespace: Return the files that could not be removed.

Author(s)

R implementation and documentation: Manos Papadakis <papadakm95@gmail.com>.

```

Inverse Gaussian regression with a log-link

Inverese Gaussian regression with a log-link

Description

Inverse Gaussian regression with a log-link.

Usage

```
invgauss.reg(y, x, tol = 1e-07, maxiters = 100)
```

Arguments

y	The dependent variable, a numerical variable with non negative numbers.
x	A matrix or data.frame with the indendent variables.
tol	The tolerance value to terminate the Newton-Raphson algorithm.
maxiters	The maximum number of iterations that can take place in the regression.

Details

An inverse Gaussian regression with a log-link is fitted.

Value

A list including:

i	The number of iterations required by the Newton-Raphson
loglik	The log-likelihood value.
deviance	The deviance value.
phi	The dispersion parameter (ϕ) of the regression. This is necessary if you want to perform an F hypothesis test for the significance of one or more independent variables.
be	The regression coefficients

Inverse of a symmetric positive definite matrix

Inverse of a symmetric positive definite matrix

Description

Inverse of a symmetric positive definite matrix.

Usage

```
spdinv(A)
```

Arguments

A	A square positive definite matrix.

Details

After calculating the Cholesky decomposition of the matrix we use this upper triangular matrix to invert the original matrix.

Value

The inverse of the input matrix.

Iterator *Iterator*

Description

A way to traverse a list, data.frame, matrix or vector.

Usage

```
iterator(x,method="ceil",type="vector",by=1)
## S3 method for class 'iterator'
print(x,...)
## S3 replacement method for class 'iterator'
Elem(x) <- value
Elem(x)
Elem(x) <- value
## S3 method for class 'iterator'
Elem(x)
## S3 method for class 'iterator'
x == y
## S3 method for class 'iterator'
x != y
```

Arguments

x	A variable with any type, or iterator object.
value	An value depending the method of the iterator.
y	An iterator.
method	Method of the iterator class. One of "ceil","col","row".
type	One of "vector","matrix","data.frame","list".
by	An integer value to iterate through element.
...	Anything the user want.

Details

iterator: is an object that helps a programmer to traverse the given object.

print.iterator: print an object of class iterator.

"Elem<-": access to element and change the value.

Elem: access to element.

Value

An object of class "iterator". This object holds 4 fields:

copy: deep copy of iterator. end: get iterator tha have access to points to the last element. equals: equality of iterators nextElem: move iterator to point to the next element using argument "by". prevElem: move iterator to point to the previous element using argument "by".

s <- s + Elem(x)
x$nextElem()
}

all.equal(s,sum(y))
```

`James multivariate version of the t-test`

James multivariate version of the t-test

Description

James test for testing the equality of two population mean vectors without assuming equality of the covariance matrices.

Usage

```
james(y1, y2, a = 0.05, R = 1)
```

Arguments

`y1`	A matrix containing the Euclidean data of the first group.
`y2`	A matrix containing the Euclidean data of the second group.
`a`	The significance level, set to 0.05 by default.
`R`	If R is 1 the classical James test is returned. If R is 2 the MNV modficiation is implemented.

Details

Multivariate analysis of variance without assuming equality of the covariance matrices. The p-value can be calculated either asymptotically or via bootstrap. The James test (1954) or a modification proposed by Krishnamoorthy and Yanping (2006) is implemented. The James test uses a corected chi-square distribution, whereas the modified version uses an F distribution.

Value

A list including:

`note`	A message informing the user about the test used.
`mesoi`	The two mean vectors.

info	The test statistic, the p-value, the correction factor and the corrected critical value of the chi-square distribution if the James test has been used or, the test statistic, the p-value, the critical value and the degrees of freedom (numerator and denominator) of the F distribution if the modified James test has been used.

k nearest neighbours algorithm (k-NN)

k nearest neighbours algorithm (k-NN)

Description

k nearest neighbours algorithm (k-NN).

Usage

```
knn(xnew, y, x, k, dist.type = "euclidean", type = "C", method = "average",
freq.option = 0, mem.eff = FALSE)
```

Arguments

xnew	The new data, new predictor variable values. A matrix with numerical data.
y	A vector with the response variable, whose values for the new data we wish to predict. This can be numerical data, factor or discrete, 0, 1, ... The latter two cases are for classification.
x	The dataset. A matrix with numerical data.

`k`	The number of nearest neighbours to use. The number can either be a single value or a vector with multiple values.
`dist.type`	The type of distance to be used. Either \"euclidean\" or \"manhattan\".
`type`	If your response variable \"y\" is numerical data, then this should be \"R\" (regression). If \"y\" is in general categorical, factor or discrete set this argument to \"C\" (classification).
`method`	In case you have regression (type = \"R\") you want a way to summarise the prediction. If you want to take the average of the reponses of the k closest observations, type \"average\". For the median, type \"median\" and for the harmonic mean, type \"harmonic\".
`freq.option`	If classification (type = \"C\") and ties occur in the prediction, more than one class has the same number of k nearest neighbours, in which case there are two strategies available: Option 0 selects the first most frequent encountered. Option 1 randomly selects the most frequent value, in the case that there are duplicates.
`mem.eff`	Boolean value indicating a conservative or not use of memory. Lower usage of memory/Having this option on will lead to a slight decrease in execution speed and should ideally be on when the amount of memory in demand might be a concern.

Details

The concept behind k-NN is simple. Suppose we have a matrix with predictor variables and a vector with the response variable (numerical or categorical). When a new vector with observations (predictor variables) is available, its corresponding response value, numerical or category is to be predicted. Instead of using a model, parametric or not, one can use this ad hoc algorithm.

The k smallest distances between the new predictor variables and the existing ones are calculated. In the case of regression, the average, median or harmonic mean of the corresponding respone values of these closest predictor values are calculated. In the case of classification, i.e. categorical response value, a voting rule is applied. The most frequent group (response value) is where the new observation is to be allocated.

Value

A matrix whose number of columns is equal to the size of k. If in the input you provided there is just one value of k, then a matrix with one column is returned containing the predicted values. If more than one value was supplied, the matrix will contain the predicted values for every value of k.

k-NN algorithm using the arc cosinus distance

k-NN algorithm using the arc cosinus distance

Description

It classifies new observations to some known groups via the k-NN algorithm.

Usage

```
dirknn(xnew, x, y, k, type = "C", parallel = FALSE)
```

Arguments

xnew	The new data whose membership is to be predicted, a numeric matrix with unit vectors. In case you have one vector only make it a row vector (i.e. matrix with one row).
x	The data, a numeric matrix with unit vectors.
k	The number of nearest neighbours. It can also be a vector with many values.
y	A numerical vector representing the class or label of each vector of x. 1, 2, 3, and so on. It can also be a numerical vector with data in order to perform regression.
type	If your response variable y is numerical data, then this should be "R" (regression) or "WR" for distance weighted based nearest neighbours. If y is in general categorical set this argument to "C" (classification) or to "WC" for distance weighted based nearest neighbours.

`parallel` Do you want th ecalculations to take place in parallel? The default value is FALSE.

Details

The standard algorithm is to keep the k nearest observations and see the groups of these observations. The new observation is allocated to the most frequent seen group. The non standard algorithm is to calculate the classical mean or the harmonic mean of the k nearest observations for each group. The new observation is allocated to the group with the smallest mean distance.

If you want regression, the predicted value is calculated as the average of the responses of the k nearest observations.

Value

A matrix with the predicted group(s). It has as many columns as the values of k.

```

Limited number of eigenvalues and eigenvectors of a symmetric matrix

Limited number of eigenvalues and eigenvectors of a symmetric matrix

---

Description

Limited number of eigenvalues and eigenvectors of a symmetric matrix.

Usage

```
eigen.sym(A, k, vectors = TRUE)
```

Arguments

`A`	A symmetric matrix.
`k`	The number of eigenvalues and eigenvectors to extract.
`vectors`	A flag that indicates if the eigenvectors will be returned (default: vectors = True)

Details

The function calls the same function from the Armadillo library in C++. It is quite faster than R's built in function "eigen" if the number of eigenvalues and eigenvectors (argument k) is small.

The k largest, in magnitude, eigenvalues are returned. Hence, if the matrix is not positive definite you may get negative eigenvalues as well. So, it is advised to use it with positive definite matrices.

Value

A list including:

`values`	The eigenvalues.
`vectors`	The eigenvectors.

Author(s)

Armadillo library in C++ and Stefanos Fafalios and Manos Papadakis.

R implementation and documentation: Stefanos Fafalios <stefanosfafalios@gmail.com> and Manos Papadakis <papadakm95@gmail.com>.

x <- s <- NULL
```

Linear models for large scale data

Linear models for large scale data

Description

Linear models for large scale data.

Usage

```
lmfit(x, y, w = NULL)
```

Arguments

x	The design matrix with the data, where each column refers to a different sample of subjects. You must supply the design matrix, with the column of 1s. This function is the analogue of lm.fit and .lm.fit.
y	A numerical vector or a numerical matrix.
w	An optional numerical vector with weights. Note that if you supply this, the function does not make them sum to 1. So, you should do it.

Details

We have simply exploitted R's powerful function and managed to do better than .lm.fit which is a really powerful function as well. This is a bare bones function as it returns only two things, the coefficients and the residuals. .lm.fit returns more and lm.fit even more and finally lm returns too much. The motivatrion came form this site https://m-clark.github.io/docs/fastr.html . We changed the function a bit.

Value

A list including:

be	The beta coefficients.
residuals	The residuals of the linear model(s).

Examples

```
n <- 200  ;  p <- 5
X <- matrnorm(n, p)
y <- rnorm(n)
a1 <- .lm.fit(X, y)
a2 <- lmfit(X, y)
x <- NULL
```

`Logistic and Poisson regression models`
Logistic and Poisson regression models

Description

Logistic and Poisson regression models.

Usage

```
glm_logistic(x, y, full = FALSE,tol = 1e-09, maxiters = 100)
glm_poisson(x, y, full = FALSE,tol = 1e-09)
```

Arguments

`x`	A matrix with the data, where the rows denote the samples (and the two groups) and the columns are the variables. This can be a matrix or a data.frame (with factors).
`y`	The dependent variable; a numerical vector with two values (0 and 1) for the logistic regression or integer values, 0, 1, 2,... for the Poisson regression.
`full`	If this is FALSE, the coefficients and the deviance will be returned only. If this is TRUE, more information is returned.
`tol`	The tolerance value to terminate the Newton-Raphson algorithm.
`maxiters`	The max number of iterations that can take place in each regression.

Details

The function is written in C++ and this is why it is very fast.

Value

When full is FALSE a list including:

`be`	The regression coefficients.
`devi`	The deviance of the model.

When full is TRUE a list including:

`info`	The regression coefficients, their standard error, their Wald test statistic and their p-value.
`devi`	The deviance.

b2 <- glm(y ~ x, poisson)

x<-y<-a1<-a2<-b1<-b2<-NULL
```

Logistic or Poisson regression with a single categorical predictor

Logistic or Poisson regression with a single categorical predictor

---

Description

Logistic or Poisson regression with a single categorical predictor.

Usage

```
logistic.cat1(y, x, logged = FALSE)
poisson.cat1(y, x, logged = FALSE)
```

Arguments

y	A numerical vector with values 0 or 1.
x	A numerical vector with discrete numbers or a factor variable. This is suppose to be a categorical predictor. If you supply a continuous valued vector the function will obviously provide wrong results. **Note:** For the "binomial.anova" if this is a numerical vector it must contain strictly positive numbers, i.e. 1, 2, 3, 4, ..., no zeros are allowed.
logged	Should the p-values be returned (FALSE) or their logarithm (TRUE)?

Details

There is a closed form solution for the logistic regression in the case of a single predictor variable. See the references for more information.

Value

`info`	A matrix similar to the one produced by the glm command. The estimates, their standard error, the Wald value and the relevant p-value.
`devs`	For the logistic regression case a vector with the null and the residual deviances, their difference and the significance of this difference.
`res`	For the Poisson regression case a vector with the log likelihood ratio test statistic value and its significance.

system.time( a2 <- glm(y ~ x, poisson) )
a1   ;  a2

x<-y<-a1<-a2<-NULL
```

`Lower and Upper triangular of a matrix`
Lower and Upper triangular of a matrix

Description

Lower/upper triangular matrix.

Usage

```
lower_tri(x, suma = FALSE, diag = FALSE)
upper_tri(x, suma = FALSE, diag = FALSE)
lower_tri.assign(x, v, diag = FALSE)
upper_tri.assign(x, v, diag = FALSE)
```

Arguments

x	A matrix with data **or** a vector with 2 values which is the dimension of the logical matrix to be returned with the upper or lower triangular filled with "TRUE".
v	A numeric vector for assign to the lower/upper triangular.
suma	A logical value for returning the sum of the upper or lower triangular. By default is "FALSE". Works only **if** argument "x" is matrix.
diag	A logical value include the diagonal to the result.

Value

Get a lower/upper triangular logical matrix with values **TRUE/FALSE**, a vector with the values of a lower/upper triangular, the sum of the upper/lower triangular if suma is set **TRUE** or assign to the lower/upper (only for large matrices) triangular. You can also include diagonal with any operation if argument diag is set to "TRUE".

x<-NULL
```

`Mahalanobis distance` *Mahalanobis distance*

Description

Mahalanobis distance.

Usage

```
mahala(x, mu, sigma, ischol = FALSE)
```

Arguments

`x`	A matrix with the data, where rows denotes observations (vectors) and the columns contain the variables.
`mu`	The mean vector.
`sigma`	The covariance or any square symmetric matrix.
`ischol`	A boolean variable set to true if the Cholesky decomposition of the covariance matrix is supplied in the argument \"sigma\".

Value

A vector with the Mahalanobis distances.

`Many (and one) area under the curve values`

Many area under the curve values

Description

Many area under the curve values.

Usage

```
colaucs(group, preds)
auc(group, preds)
```

Arguments

`group`	A numerical vector with two values, one of which must be strictly 1.
`preds`	A numerical matrix with scores, probabilities or any other measure. In the case of auc this is a vector.

Details

The AUCs are calculated column-wise or just an AUC if the vector function is used.

Value

A vector with length equal to the number of columns of the "preds" argument, with the AUC values for each column. If the "auc" function is used then a signle number is returned.

a <- colaucs(ina, x)
b <- auc(ina, x[, 1])
x <- NULL
```

`Many 2 sample proportions tests`

Many 2 sample proportions tests

Description

It performs very many 2 sample proportions tests.

Usage

```
proptests(x1, x2, n1, n2)
```

Arguments

x1	A vector with the successes of the one group.
x2	A vector with the successes of the one group.
n1	A vector with the number of trials of the one group.
n2	A vector with the number of trials of the one group.

Details

The 2-sample proportions test is performed for each pair of proportions of teh two groups.

Value

A matrix with the proportions of each group (two columns), the test statistic and the p-value of each test.

See Also

`ttests`, `ftests`, `colVars`

Examples

```
## 10000 variables, hence 10000 t-tests will be performed
set.seed(12345)
x1 <- rpois(500, 5)
x2 <- rpois(500, 5)
n1 <- rpois(1000, 40)
n2 <- rpois(1000, 40)
a <- proptests(x1, x2, n1, n2)
mean(a[, 4]<0.05)

x1 <- rbinom(500, 500, 0.6)
x2 <- rbinom(500, 500, 0.6)
b <- proptests(x1, x2, 500, 500)
mean(b[, 4]<0.05)
```

Many 2 sample tests *Many 2 sample tests tests*

Description

It performs very many 2 sample tests.

Usage

```
ttests(x, y = NULL, ina, paired = FALSE, logged = FALSE, parallel = FALSE)
mcnemars(x, y = NULL, ina, logged = FALSE)
var2tests(x, y = NULL, ina, alternative = "unequal", logged = FALSE)
```

Arguments

x	A matrix with the data, where the rows denote the samples and the columns are the variables.
y	A second matrix with the data of the second group. If this is NULL (default value) then the argument ina must be supplied. Notice that when you supply the two matrices the procedure is two times faster.
ina	A numerical vector with 1s and 2s indicating the two groups. Be careful, the function is designed to accept only these two numbers. In addition, if your "y" is NULL, you must specify "ina".

alternative	The type of hypothesis to be checked, "equal", "greater", "less".
paired	If the groups are not independent paired t-tests should be performed and this must be TRUE, otherwise, leave it FALSE. In this case, the two groups must have equal smaple sizes, otherwise no test will be performed.
logged	Should the p-values be returned (FALSE) or their logarithm (TRUE)?
parallel	Should parallel implentations take place in C++? The default value is FALSE.

Details

For the ttests, if the groups are independent, the Welch's t-test (without assuming equal variances) is performed. Otherwise many paired t-tests are performed. The McNemar's test requires a number of observations, at least 30 would be good in order for the test to have some power and be size corect.

Value

A matrix with the test statistic, the degrees of freedom (if the groups are independent) and the p-value (or their logarithm) of each test.

x <- NULL
```

`Many analysis of variance tests with a discrete variable`
Many analysis of variance tests with a discrete variable

Description

Many analysis of variance tests with a discrete variable.

Usage

```
poisson.anovas(y, ina, logged = FALSE)
quasipoisson.anovas(y, ina, logged = FALSE)
geom.anovas(y, ina, type = 1, logged = FALSE)
```

Arguments

`y`	A numerical matrix with discrete valued data, i.e. counts for the case of the Poisson, or with 0s and 1s for the case of the Bernoulli distribution. Each column represents a variable.
`ina`	A numerical vector with discrete numbers starting from 1, i.e. 1, 2, 3, 4,... or a factor variable. This is suppose to be a categorical predictor. If you supply a continuous valued vector the function will obviously provide wrong results.
`type`	This rgument is for the geometric distribution. Type 1 refers to the case where the minimum is zero and type 2 for the case of the minimum being 1.
`logged`	Should the p-values be returned (FALSE) or their logarithm (TRUE)?

Details

This is the analysis of variance with count data. What we do is many log-likelihood ratio tests. For the quasi Poisson case we scale the difference in the deviances.

Value

A matrix with two values, the difference in the deviances (test statistic) and the relevant p-value. For the case of quasi Poisson the estimated ϕ parameter is also returned.

```
ina <- rbinom(500, 3, 0.5) + 1
## Poisson example
y <- matrix( rpois(500 * 100, 10), ncol= 100 )
system.time(a1 <- poisson.anovas(y, ina) )
y <- NULL
```

Many ANCOVAs *Many ANCOVAs*

Description

Many ANCOVAs.

Usage

```
ancovas(y, ina, x, logged = FALSE)
```

Arguments

y	A matrix with the data, where the rows denote the observations and the columns are the variables.
ina	A numerical vector with 1s, 2s, 3s and so one indicating the two groups. Be careful, the function is desinged to accept numbers greater than zero.
x	A numerical vector whose length is equal to the number of rows of y. This is the covariate.
logged	Should the p-values be returned (FALSE) or their logarithm (TRUE)?

Details

Many Analysis of covariance tests are performed. No interaction between the factor and the covariate is tested. Only the main effects. The design need not be balanced. The values of ina need not have the same frequency. The sums of squares have been adjusted to accept balanced and unbalanced designs.

Value

A matrix with the test statistic and the p-value for the factor variable and the covariate.

`Many ANOVAS for count data with Poisson or quasi Poisson models`

Many ANOVAS for count data with Poisson or quasi Poisson models

---

Description

Many ANOVAS for count data with Poisson or quasi Poisson models.

Usage

```
colpoisson.anovas(y, x, logged = FALSE)
colquasipoisson.anovas(y, x, logged = FALSE)
```

Arguments

y	A numerical vector with the data.
x	A matrix with the data, where the rows denote the samples (and the two groups) and the columns are the variables. This must be a matrix with the categorical variables as numbers, starting from 1. Poisson or quassi Poisson ANOVA takes place for each column.
logged	A boolean variable; it will return the logarithm of the pvalue if set to TRUE.

Details

Poisson or quassi Poisson ANOVA takes place at each column.

Value

A matrix with the test statistic and the (logged) p-value for each predictor variable. In the case of the quasi Poisson, the ϕ is returned as well.

Author(s)

Michail Tsagris and Manos Papadakis

Many exponential regressions

Many exponential regressions

Description

Many exponential regressions.

Usage

```
expregs(y, x, di, tol = 1e-09, logged = FALSE)
```

Arguments

y	A vector with positive data (including zeros).
x	A numerical matrix with the predictor variables.
di	A vector of size equal to that of y with 0s and 1s indicating censoring or not respectively.
tol	The tolerance value to stop the newton-Raphson iterations. It is set to 1e-09 by default.
logged	A boolean variable; it will return the logarithm of the pvalue if set to TRUE.

Details

We have implemented the newton-Raphson in order to avoid unnecessary calculations.

Value

A matrix with three columns, the test statistic, its associated (logged) p-value and the BIC of each model.

x <- NULL
```

Many F-tests with really huge matrices

Many F-tests with really huge matrices

Description

Many F-tests with really huge matrices.

Usage

```
list.ftests(x, logged = FALSE)
```

Arguments

x	A list with many big size matrices. Each element of the list contains a matrix. This is the ftests function but with really huge matrices, which cannot be loaded into R as a single matrix.
logged	Should the p-values be returned (FALSE) or their logarithm (TRUE)?

Details

The Welch's F-test (without assuming equal variances) is performed just like in the "ftests" function. The difference is that you have a really huge matrix which you cannot load into R. In the "ftests" function, the argument "ina" denotes the different groups. Here, you "cut" the matrix into smaller ones, each of which denotes a different group and put them in a list.

Value

A matrix with the test statistic and the p-value of each test.

Examples

```
x <- matrnorm(300, 500)
ina <- rbinom(300, 2, 0.6) + 1
a <- list()
a[[ 1 ]] <- x[ina == 1, ]
a[[ 2 ]] <- x[ina == 2, ]
a[[ 3 ]] <- x[ina == 3, ]
mod <- list.ftests(a)
z <- NULL
a <- NULL
```

Many G-square and Chi-square tests of indepedence

Many G-square tests of indepedence

Description

Many G-square tests of indepdence with and without permutations.

Usage

```
g2tests(data, x, y, dc)
g2tests_perm(data, x, y, dc, nperm)
chi2tests(data, x, y, dc)
```

Arguments

`data`	A numerical matrix with the data. **The minimum must be 0, otherwise the function can crash or will produce wrong results**. The data must be consecutive numbers.
`x`	An integer number or a vector of integer numbers showing the other variable(s) to be used for the G^2 test of independence.
`y`	An integer number showing which column of data to be used.
`dc`	A numerical value equal to the number of variables (or columns of the data matrix) indicating the number of distinct, unique values (or levels) of each variable. Make sure you give the correct numbers here, otherwise the degrees of freedom will be wrong.
`nperm`	The number of permutations. The permutations test is slower than without permutations and should be used with small sample sizes or when the contigency tables have zeros. When there are few variables, R's "chisq.test" function is faster, but as the number of variables increase the time difference with R's procedure becomes larger and larger.

Details

The function does all the pairwise G^2 test of independence and gives the position inside the matrix. The user must build the associations matrix now, similarly to the correlation matrix. See the examples of how to do that. The p-value is not returned, we leave this to the user. See the examples of how to obtain it.

Value

A list including:

`statistic`	The G^2 or χ^2 test statistic for each pair of variables.
`pvalue`	This is returned when you have selected the permutation based G^2 test.
`x`	The row or variable of the data.
`y`	The column or variable of the data.
`df`	The degrees of freedom of each test.

a<-b<-data<-NULL
```

Many Gini coefficients

Many Gini coefficients

Description

Many Gini coefficients.

Usage

```
ginis(x)
```

Arguments

x	A matrix with non negative data. The rows are observations and the columns denote the variables.

Details

We have implemented the fast version of the Gini coefficient. See wikipedia for more details.

Value

A vector with the Gini coefficient, one for each variable.

Author(s)

Michail Tsagris

R implementation and documentation: Michail Tsagris <mtsagris@uoc.gr> and Manos Papadakis <papadakm95@gmail.com>.

`Many hypothesis tests for two means of percentages`
Many hypothesis tests for two means of percentages

Description

Many hypothesis tests for two means of percentages.

Usage

```
percent.ttests(x, y, logged = FALSE)
```

Arguments

`x`	A numericalmatrix with the percentages of the first sample. Any value between 0 and 1 (inclusive) is allowed.
`y`	A numerical matrix with the percentages of the first sample. Any value between 0 and 1 (inclusive) is allowed.
`logged`	Should the p-values be returned (FALSE) or their logarithm (TRUE)?

Details

This is the `prop.reg` but with a single categorical predictor which has two levels only. It is like a t-test for the means of two samples haivng percentages.

Value

A matrix with three columns, the phi parameter, the test statistic and its associated p-value.

Many moment and maximum likelihood estimations of variance components

Many moment and maximum likelihood estimations of variance components

---

Description

Many moment and maximum likelihood estimations of variance components.

Usage

```
colvarcomps.mom(x, id, parallel = FALSE)
colvarcomps.mle(x, id, ranef = FALSE, tol= 1e-08, maxiters = 100,
parallel = FALSE)
```

Arguments

x	A matrix with the data, where each column refers to a different sample of subjects.
id	A numerical vector indicating the subject. You must put consecutive numbers and no zero values. Alternatively this can be a factor variable.
ranef	Do you also want the random effects to be returned? TRUE or FALSE.
tol	The tolerance level to terminate the golden ratio search.
maxiters	The maximum number of iterations to perform.
parallel	Should the computations run in parallel? TRUE or FALSE.

Details

Note that the "colvarcomp.mom" works for **balanced designs only**, i.e. for each subject the same number of measurements have been taken. The "colvarcomps.mle" works for unbalanced as well.

The variance components, the variance of the between measurements and the variance of the within are estimated using moment estimators. The "colvarcomps.mom" is the moment analogue of a random effects model which uses likelihood estimation ("colvarcomps.mle"). It is much faster, but can give negative variance of the random effects, in which case it becomes zero.

The maximum likelihood version is a bit slower (try youselves to see the difference), but statistically speaking is to be preferred when small samples are available. The reason why it is only a little

bit slower and not a lot slower as one would imagine is because we are using a closed formula to calculate the two variance components (Demidenko, 2013, pg. 67-69). Yes, there are closed formulas for linear mixed models.

Value

For the "colvarcomps.mom": A matrix with 5 columns, The MSE, the estimate of the between variance, the variance components ratio and a 95% confidence for the ratio.

For the "colvarcomps.mle": **If ranef = FALSE** a list with a single component called "info". That is a matrix with 3 columns, The MSE, the estimate of the between variance and the log-likelihood value. **If ranef = TRUE** a list including "info" and an extra component called "ranef" containing the random effects. It is a matrix with the same number of columns as the data. Each column contains the randome effects of each variable.

x <- NULL
```

Many multi-sample tests

Many multi-sample tests

Description

Many multi-sample tests.

Usage

```
ftests(x, ina, logged = FALSE)
anovas(x, ina, logged = FALSE)
vartests(x, ina, type = "levene", logged = FALSE)
block.anovas(x, treat, block, logged = FALSE)
```

Arguments

x	A matrix with the data, where the rows denote the observations (and the two groups) and the columns are the variables.
ina	A numerical vector with 1s, 2s, 3s and so one indicating the two groups. Be careful, the function is desinged to accept numbers greater than zero. Alternatively it can be a factor variable.
type	This is for the variances test and can be either "levene" or "bf" corresponding to Levene's or Brown-Forsythe's testing procedure.
treat	In the case of the blocking ANOVA this argument plays the role of the "ina" argument.
block	This item, in the blocking ANOVA denotes the subjects which are the same. Similarly to "ina" a numeric vector with 1s, 2s, 3s and so on.
logged	Should the p-values be returned (FALSE) or their logarithm (TRUE)?

Details

The Welch's F-test (without assuming equal variances) is performed with the "ftests" function. The "anovas" function perform the classical (Fisher's) one-way analysis of variance (ANOVA) which assumes equal variance across the groups.

The "vartests" perform hypothesis test for the equality of the variances in two ways, either via the Levene or via the Brown-Forshythe procedure. Levene's test employs the means, whereas the Brown-Forsythe procedure employs the medians and is therefore more robust to outliers. The "var2tests" implement the classical F test.

The "block.anova" is the ANOVA with blocking, randomised complete block design (RCBD). In this case, for every combination of the block and treatment values, there is only one observation. The mathematics are the same as in the case of two way ANOVA, but the assumptions different and the testing procedure also different. In addition, no interaction is present.

Value

A matrix with the test statistic and the p-value of each test.

Author(s)

Michail Tsagris.

R implementation and documentation: Michail Tsagris <mtsagris@uoc.gr> and Manos Papadakis <papadakm95@gmail.com>.

a2 <- anovas(x, ina)
a3 <- vartests(x, ina)
x <- NULL
```

Many multivariate simple linear regressions coefficients

Many multivariate simple linear regressions coefficients

Description

Many multivariate simple linear regressions coefficients.

Usage

```
mvbetas(y, x, pvalue = FALSE)
```

Arguments

y	A matrix with the data, where rows denotes the observations and the columns contain the dependent variables.
x	A numerical vector with one continuous independent variable only.
pvalue	If you want a hypothesis test that each slope (beta coefficient) is equal to zero set this equal to TRUE. It will also produce all the correlations between y and x.

Details

It is a function somehow opposite to the allbetas. Instead of having one y and many xs we have many ys and one x.

Value

A matrix with the constant (alpha) and the slope (beta) for each simple linear regression. If the p-value is set to TRUE, the correlation of each y with the x is calculated along with the relevant p-value.

Author(s)

Michail Tsagris

R implementation and documentation: Michail Tsagris <mtsagris@uoc.gr> and Manos Papadakis <papadakm95@gmail.com>.

See Also

y <- matrnorm(100, 100)
x <- rnorm(100)
a <- mvbetas(y, x, pvalue = FALSE)
b <- matrix(nrow = 100, ncol = 2)
z <- cbind(1, x)

system.time( a <- mvbetas(y, x) )
b[2, ] <- coef( lm.fit( z, y[, 1] ) )
b[2, ] <- coef( lm.fit( z, y[, 2] ) )
x <- NULL
```

Many non parametric multi-sample tests

Many multi-sample tests

Description

Many multi-sample tests.

Usage

```
kruskaltests(x, ina, logged = FALSE)
cqtests(x, treat, block, logged = FALSE)
```

Arguments

x	A matrix with the data, where the rows denote the samples (and the two groups) and the columns are the variables.
ina	A numerical vector with 1s, 2s, 3s and so one indicating the two groups. Be careful, the function is desinged to accept numbers greater than zero.
treat	In the case of the Cochran's Q test, this argument plays the role of the "ina" argument.
block	This item denotes the subjects which are the same. Similarly to "ina" a numeric vector with 1s, 2s, 3s and so on.
logged	Should the p-values be returned (FALSE) or their logarithm (TRUE)?

Details

The "kruskaltests" performs the Kruskal-Wallis non parametric alternative to analysis of variance test. The "cqtests" performs the Cocrhan's Q test for the equality of more than two groups whose values are strictly binary (0 or 1). This is a generalisation of the McNemar's test in the multi-sample case.

Value

A matrix with the test statistic and the p-value of each test.

Author(s)

Michail Tsagris

R implementation and documentation: Michail Tsagris <mtsagris@uoc.gr> and Manos Papadakis <papadakm95@gmail.com>.

x <- matrix( rbinom(300 * 200, 1, 0.6), ncol = 200 )
treat <- rep(1:3, each = 100)
block <- rep(1:3, 100)
system.time( cqtests(x, treat, block) )
x <- NULL
```

`Many odds ratio tests` *Many odds ratio tests*

Description

It performs very many odds ratio tests.

Usage

```
odds(x, y = NULL, ina, logged = FALSE)
```

Arguments

`x`	A matrix with the data, where the rows denote the observations and the columns are the variables. They must be 0s and 1s only.
`y`	A second matrix with the data of the second group. If this is NULL (default value) then the argument ina must be supplied. Notice that when you supply the two matrices the procedure is two times faster. They must be 0s and 1s only.
`ina`	A numerical vector with 1s and 2s indicating the two groups. Be careful, the function is designed to accept only these two numbers. In addition, if your "y" is NULL, you must specify "ina".
`logged`	Should the p-values be returned (FALSE) or their logarithm (TRUE)?

Details

Many odds ratio tests are performed.

Value

A matrix with the test statistic and the p-value (or their logarithm) of each test.

Author(s)

Michail Tsagris

`Many one sample goodness of fit tests for categorical data`
Many one sample goodness of fit tests for categorical data

Description

Many one sample goodness of fit tests for categorical data.

Usage

```
cat.goftests(x, props, type = "gsquare", logged = FALSE)
```

Arguments

`x`	A matrix with the data, where the rows denote the samples and the columns are the variables. The data must be integers and be of the form 1, 2, 3, and so on. The minimum must be 1, and not zero.
`props`	The assumed distribution of the data. A vector or percentages summing to 1.
`type`	Either Pearson's χ^2 test ("chisquare") is used or the G^2 test ("qsquare", default value).
`logged`	Should the p-values be returned (FALSE) or their logarithm (TRUE)?

Details

Given a matrix of integers, where each column refers to a sample, the values of a categorical variable the function tests wether these values can be assumed to fit a specific distribution.

Value

A matrix with the test statistic and the p-value of each test.

Author(s)

Michail Tsagris

R implementation and documentation: Michail Tsagris <mtsagris@uoc.gr> and Manos Papadakis <papadakm95@gmail.com>.

## can we assume that each column comes from a distribution  whose mass is given by props?
system.time( cat.goftests(x, props) )
a1 <- cat.goftests(x, props)  ## G-square test
a2 <- cat.goftests(x, props, type = "chisq")  ## Chi-square test
cor(a1, a2)
mean( abs(a1 - a2) )
x <- NULL
```

Many one sample tests *Many one sample tests*

Description

Many one sample tests.

Usage

```
proptest(x, n, p, alternative = "unequal", logged = FALSE)
ttest(x, m, alternative = "unequal", logged = FALSE, conf = NULL)
vartest(x, sigma, alternative = "unequal", logged = FALSE, conf = NULL)
```

Arguments

x	A matrix with numerical data. Each column of the matrix corresponds to a sample, or a group. In the case of the "proptest" this is a vector integers ranging from 0 up to n. It is the number of "successes".
n	This is for the "proptest" only and is a vector with integer numbers specifying the number of tries for the proptest. Its size is equal to the size of x.
p	A vector with the assumed probabilities of success in the "proptest". Its size is equal to the number of colums of the matrix x.
m	A vector with the assumed means. Its size is equal to the number of colums of the matrix x.
sigma	A vector with assumed variances. Its size is equal to the number of colums of the matrix x.
alternative	The type of hypothesis to be checked. Equal to ("unequal"), grater than("greater") or less than ("less") the assumed parameter.
logged	Should the p-values be returned (FALSE) or their logarithm (TRUE)?
conf	If you want confidence intervals to be returned specify the confidence level, otherwise leave it NULL.

Details

Despite the functions having been written in R, they are very fast.

Value

For all tests except for the "sftests" a matrix with two colums, the test statistic and the p-value respectively.

```

Many random intercepts LMMs for balanced data with a single identical covariate.

Many random intercepts LMMs for balanced data with a single identical covariate

---

Description

Many random intercepts LMMs for balanced data with a single identical covariate.

Usage

```
colrint.regbx(y, x, id)
```

Arguments

y	A numerical matrix with the data. The subject values.
x	A numerical vector with the same length as the number of rows of y indicating the fixed predictor variable. Its values are the same for all levels of y. An example of this x is time which is the same for all subjects.
id	A numerical variable with 1, 2, ... indicating the subject.

Details

This is a special case of a balanced random intercepts model with a compound symmetric covariance matrix and one single covariate which is constant for all replicates. An example, is time, which is the same for all subjects. Maximum likelihood estimation has been performed. In this case the mathematics exist in a closed formula (Demidenko, 2013, pg. 67-69).

This is the generalistion of `rint.regbx` to matrices. Assume you have many observations, gene expressions over time for example, and you want to calculate the random effects or something else for each expression. Instead of using a "for" loop with `rint.regbx` function we have used amtrix operations to make it even faster.

Value

A list including:

info	A matrix with the random intercepts variance (between), the variance of the errors (within), the log-likelihood, the deviance (twice the log-likelihood) and the BIC. In the case of "rint.reg" it also includes the number of iterations required by the generalised least squares.
be	The estimated regression coefficients, which in the case of "rint.regbx" are simply two: the constant and the slope (time effect).
ranef	A matrix with random intercepts effects. Each row corresponds to a column in y. Instead of having a matrix with the same number of columns as y we return a transposed matrix.

Author(s)

Michail Tsagris

R implementation and documentation: Michail Tsagris <mtsagris@uoc.gr> and Manos Papadakis <papadakm95@gmail.com>.

system.time( a<- colrint.regbx(y, x, id) )
```

`Many regression based tests for single sample repeated measures`
Many regression based tests for single sample repeated measures

---

Description

Many regression based tests for single sample repeated measures.

Usage

```
rm.lines(y, x, logged = FALSE)
rm.anovas(y, x, logged = FALSE)
```

Arguments

`y`	A matrix with the data, where each column refers to a different sample of subjects. For example, the first column is the repeated measurements of a sample of subjects, the second column contains repeated measurements of a second sample of subjects and so on. Within each column, the measurements of each subjects are stacked one upon the other. Say for examples there are n subjects and each of them has been measured d times (in time or at different experimental conditions). We put these in a matrix with just one column. The first d rows are the measurements of subject 1, the next d rows are the measurements of subject 2 and so on.
`x`	A numerical vector with time (usually) or the the predictor variable. For example the temperature, or the pressure. See the details for more information. Its length is equal to the time points for example, i.e. it must not have the same length as the number of rows of y. For the "rm.lines" this is a continuous variable. For the "rm.anovas" this is treated as a categorical variable, indicating say the type of experimental condition, but no difference between the points is important. Hence, for this function only, x can also be a facto variable.
`logged`	Should the p-values be returned (FALSE) or their logarithm (TRUE)?

Details

In order to see whether the repeated measurements are associated with a single covariate, e.g. time we perform many regressions and each time calculate the slope. For each subject, its regression slope with the covariate is calculated. In the end a t-test for the hypothesis that the average slopes is zero is performed. The regression slopes ignore that the measurements are not independent, but

note that the slopes are independent, because they come from different subjects. This is a simple, summary statistics based approach found in Davis (2002), yet it can provide satisfactory results.

The second approach ("rm.anovas") found in Davis (2002) is the usual repeated measures ANOVA. In this case, suppose you have taken measurements on one or more variables from the same group of people. See the example below on how to put such data.

Value

A matrix with the test statistic (t-test) and its associated p-value.

Many score based regressions
Many score based regressions

Description

Many score based GLM regressions.

Usage

```
score.glms(y, x, oiko = NULL, logged = FALSE)
score.multinomregs(y, x, logged = FALSE)
score.negbinregs(y, x, type = 1, logged = FALSE)
score.weibregs(y, x, logged = FALSE)
score.betaregs(y, x, logged = FALSE)
score.gammaregs(y, x, logged = FALSE)
score.expregs(y, x, logged = FALSE)
score.invgaussregs(y, x, logged = FALSE)
score.ztpregs(y, x, logged = FALSE)
score.geomregs(y, x, logged = FALSE)
```

Arguments

y	A vector with either discrete or binary data for the Poisson, geometric, or negative binomial and binary logistic regressions, respectively. A vector with discrete values or factor values for the multinomial regression. If the vector is binary and choose multinomial regression the function checks and transfers to the binary logistic regression. For the Weibull, gamma, inverse Gaussian and exponential regressions they must be strictly positive data, lifetimes or durations for example. For the beta regression they must be numbers between 0 and 1. For the zero truncated Poisson regression (score.ztpregs) they must be integer valued data strictly greater than 0.
x	A matrix with data, the predictor variables.
oiko	This can be either "poisson" or "binomial". If you are not sure leave it NULL and the function will check internally.
type	This argument is for the negative binomial distribution. In the negative binomial you can choose which way your prefer. Type 1 is for smal sample sizes, whereas type 2 is for larger ones as is faster.
logged	A boolean variable; it will return the logarithm of the pvalue if set to TRUE.

Details

Instead of maximising the log-likelihood via the Newton-Raphson algorithm in order to perform the hypothesis testing that $\beta_i = 0$ we use the score test. This is dramatcially faster as no model needs to be fitted. The first derivative (score) of the log-likelihood is known and in closed form and under the null hypothesis the fitted values are all equal to the mean of the response variable y. The variance of the score is also known in closed form. The test is not the same as the likelihood ratio test. It is size correct nonetheless but it is a bit less efficient and less powerful. For big sample sizes though (5000 or more) the results are the same. We have seen via simulation studies is that it is size correct to large sample sizes, at elast a few thousands. You can try for yourselves and see that even with 500 the results are pretty close. The score test is pretty faster than the classical log-likelihood ratio test.

Value

A matrix with two columns, the test statistic and its associated p-value. For the Poisson and logistic regression the p-value is derived via the t distribution, whereas for the multinomial regressions via the χ^2 distribution.

x <- NULL
```

`Many Shapiro-Francia normality tests`
Many Shapiro-Francia normality tests

Description

Many Shapiro-Francia normality tests.

Usage

```
sftests(x, logged = FALSE)
sftest(x, logged = FALSE)
```

Arguments

`x`	A matrix with the data, where the rows denote the observations and the columns are the variables. In the case of a single sample, then this must be a vector and "sftest" is to be used.
`logged`	Should the p-values be returned (FALSE) or their logarithm (TRUE)?

Details

The Shapiro-Francia univariate normality test is performed for each column (variable) of the matrix x.

Value

A matrix with the squared correlation between the ordered values and the standard normal ordered statistics, the test statistic and the p-value of each test. If the "sftest" has been used, the output is a vector with these three elements.

res<-sftest(x)
```

Many simple circular or angular regressions

Many simple circular or angular regressions

Description

Many regressions with one circular dependent variable and one Euclidean independent variable.

Usage

```
spml.regs(y, x, tol = 1e-07, logged = FALSE, maxiters = 100, parallel = FALSE)
```

Arguments

y	The dependent variable, it can be a numerical vector with data expressed in radians or it can be a matrix with two columns, the cosinus and the sinus of the circular data. The benefit of the matrix is that if the function is to be called multiple times with the same response, there is no need to transform the vector every time into a matrix.
x	A matrix with independent variable.
tol	The tolerance value to terminatate the Newton-Raphson algorithm.
logged	Do you want the logarithm of the p-value be returned? TRUE or FALSE.
maxiters	The maximum number of iterations to implement.
parallel	Do you want the calculations to take plac ein parallel? The default value if FALSE.

Details

The Newton-Raphson algorithm is fitted in these regression as described in Presnell et al. (1998). For each colum of x a circual regression model is fitted and the hypothesis testing of no association between y and this variable is performed.

Value

A matrix with two columns, the test statistics and their associated (log) p-values.

Author(s)

Michail Tsagris and Stefanos Fafalios

R implementation and documentation: Michail Tsagris <mtsagris@uoc.gr> and Stefanos Fafalios <stefanosfafalios@gmail.com>

```
x <- rnorm(100)
z <- cbind(3 + 2 * x, 1 -3 * x)
y <- cbind( rnorm(100,z[ ,1], 1), rnorm(100, z[ ,2], 1) )
y <- y / sqrt( rowsums(y^2) )
x <- matrnorm(100, 100)
a <- spml.regs(y, x)
x <- NULL
```

`Many simple geometric regressions`

Many simple geometric regressions.

Description

Many simple geometric regressions.

Usage

```
geom.regs(y, x, tol = 1e-07, type = 1, logged = FALSE, parallel = FALSE, maxiters = 100)
```

Arguments

`y`	The dependent variable, count data.
`x`	A matrix with the indendent variables.
`tol`	The tolerance value to terminate the Newton-Raphson algorithm.
`type`	Type 1 refers to the case where the minimum is zero and type 2 for the case of the minimum being 1.
`logged`	A boolean variable; it will return the logarithm of the pvalue if set to TRUE.
`parallel`	Do you want this to be executed in parallel or not. The parallel takes place in C++, and the number of threads is defined by each system's availiable cores.
`maxiters`	The max number of iterations that can take place in each regression.

Details

Many simple geometric regressions are fitted.

Value

A matrix with the test statistic values, their relevant (logged) p-values and the BIC values.

Author(s)

Stefanos Fafalios

R implementation and documentation: Stefanos Fafalios <stefanosfafalios@gmail.com>

y <- rgeom(100, 0.6)
x <- matrix( rnorm(100 * 50), ncol = 50)
a <- geom.regs(y, x)
x <- NULL
```

Many simple linear mixed model regressions

Many simple linear mixed model regressions

Description

Many simple linear mixed model regressions with random intercepts only.

Usage

```
rint.regs(y, x, id, tol = 1e-08, logged = FALSE, parallel = FALSE, maxiters = 100)
```

Arguments

y	A numerical vector with the data. The subject values, the clustered data.
x	A numerical matrix with data ,the independent variables.
id	A numerical variable with 1, 2, ... indicating the subject. Unbalanced design is of course welcome.
tol	The tolerance value to terminate the Newton-Raphson algorithm. This is set to 10^{-9} by default.
logged	Should the p-values be returned (FALSE) or their logarithm (TRUE)?
parallel	Do you want this to be executed in parallel or not. The parallel takes place in C++, and the number of threads is defined by each system's availiable cores.
maxiters	The max number of iterations that can take place in each regression.

Details

Many linear mixed models with a single covariate are fitted. We use Newton-Raphson as described in Demidenko (2013). The test statistic is the usual F-test. This model allows for random intercepts only.

Value

A two-column matrix with the test statistics (Wald statistic) and the associated p-values (or their loggarithm).

```
## not a so good example
y <- rnorm(100)
id <- sample(1:10, 100, replace = TRUE)
x <- matrix( rnorm(100 * 100), ncol = 100)
a <- rint.regs(y, x, id)
x <- NULL
```

Many simple linear regressions coefficients

Simple linear regressions coefficients

Description

Simple linear regressions coefficients.

Usage

```
allbetas(y, x, pvalue = FALSE, logged = FALSE)
```

Arguments

y	A numerical vector with the response variable.
x	A matrix with the data, where rows denotes the observations and the columns contain the independent variables.
pvalue	If you want a hypothesis test that each slope (beta coefficient) is equal to zero set this equal to TRUE. It will also produce all the correlations between y and x.
logged	A boolean variable; it will return the logarithm of the pvalue if set to TRUE.

Value

A matrix with the constant (alpha) and the slope (beta) for each simple linear regression. If the p-value is set to TRUE, the correlation of each y with the x is calculated along with the relevant test statistic and its associated p-value.

Author(s)

Michail Tsagris

R implementation and documentation: Michail Tsagris <mtsagris@uoc.gr> and Manos Papadakis <papadakm95@gmail.com>.

a <- allbetas(y, x)  ## the coefficients of each simple linear regression of y with x
x <- NULL
```

Many simple multinomial regressions

Many simple multinomial regressions.

Description

Many simple multinomial regressions.

Usage

```
multinom.regs(y, x, tol = 1e-08, logged = FALSE, parallel = FALSE, maxiters = 100)
```

Arguments

y	The dependent variable, either a numerical variable or a factor variable.
x	A matrix with the indendent variables.
tol	The tolerance value to terminate the Newton-Raphson algorithm.
logged	A boolean variable; it will return the logarithm of the pvalue if set to TRUE.
parallel	Do you want this to be executed in parallel or not. The parallel takes place in C++, and the number of threads is defined by each system's availiable cores.
maxiters	The maximum number of iterations that can take place in each regression.

Details

Many simple multinomial regressions are fitted.

Value

A matrix with the test statistic values, their relevant (logged) p-values and the BIC values.

Author(s)

Stefanos Fafalios

R implementation and documentation: Stefanos Fafalios <stefanosfafalios@gmail.com>

x <- NULL
```

Many simple regressions for positive valued data

Many simple regressions for positive valued data

Description

Many simple regressions for positive valued data.

Usage

```
normlog.regs(y, x, tol = 1e-08, logged = FALSE, parallel = FALSE, maxiters = 100)
gammaregs(y, x, tol = 1e-07, logged = FALSE, maxiters = 100)
invgauss.regs(y, x, tol = 1e-08, logged = FALSE, maxiters = 100)
```

Arguments

y	The dependent variable, a numerical variable with non negative numbers for the Gamma and inverse Gaussian regressions. For the Gaussian with a log-link zero values are allowed.
x	A matrix with the indendent variables.
tol	The tolerance value to terminate the Newton-Raphson algorithm.
logged	A boolean variable; it will return the logarithm of the pvalue if set to TRUE.
parallel	Do you want this to be executed in parallel or not. The parallel takes place in C++, therefore you do not have the option to set the number of cores.
maxiters	The maximum number of iterations that can take place in each regression.

Details

Many simple Gamma, inverse Gaussian or Gaussian regressions with a log-link are fitted.

Value

A matrix with the test statistic values and their relevant (logged) p-values.

```

```
x <- NULL
```

```
Many tests for the dispersion parameter in Poisson distribution
```
Many tests for the dispersion parameter in Poisson distribution

---

Description

Many tests for the dispersion parameter in Poisson distribution.

Usage

```
colpoisdisp.tests(y, alternative = "either", logged = FALSE)
colpois.tests(y, logged = FALSE)
```

Arguments

`y`	A numerical matrix with count data, 0, 1,...
`alternative`	Do you want to test specifically for either over or underspirsion ("either"), overdispersion ("over") or undersispersion ("under")?
`logged`	Set to TRUE if you want the logarithm of the p-value.

Value

A matrix with two columns, the test statistic and the (logged) p-value.

Author(s)

Michail Tsagris

R implementation and documentation: Michail Tsagris <mtsagris@uoc.gr> and Manos Papadakis <papadakm95@gmail.com>.

a2 <- colpoisdisp.tests(y, "either")
b2 <- colpois.tests(y)
y <- NULL
```

`Many two-way ANOVAs` *Many two-way ANOVAs*

Description

Many two-way ANOVAs.

Usage

```
twoway.anovas(y, x1, x2, interact = FALSE, logged = FALSE)
```

Arguments

y	A matrix with the data, where the rows denote the observations (and the two groups) and the columns are the variables.
x1	A numerical vector with 1s, 2s, 3s and so one indicating the two groups. Alternatively it can be a factor variable. This is the one factor.
x2	A numerical vector with 1s, 2s, 3s and so one indicating the two groups. Alternatively it can be a factor variable. This is the other factor.
interact	A boolean variable specifying whether you want to test for interaction.
logged	Should the p-values be returned (FALSE) or their logarithm (TRUE)?

Details

The classical two-way ANOVA design is performed. Note that the design must be balanced. For every combination of values of the two factors, x1 and x2 the same number of observations must exist. If that's not the case, regression models must be used.

Value

A matrix with the test statistic and the p-value of each test.

y <- NULL
```

Many univariate generalised linear models

Many univariate generalised linear regressions

Description

It performs very many univariate generalised linear regressions.

Usage

```
univglms(y, x, oiko = NULL, logged = FALSE)

univglms2(y, x, oiko = NULL, logged = FALSE)
```

Arguments

y	The dependent variable. It can be a factor or a numerical variable with two values only (binary logistic regression), a discrete valued vector (count data) corresponding to a poisson regression or a numerical vector with continuous values (normal regression).
x	A matrix with the data, where the rows denote the samples (and the two groups) and the columns are the variables. For the "univglms" only continuous variables are allowed. You are advised to standardise the data before hand to avoid numerical overflow or similar issues. If you see NaN in the outcome, this might be the case. For the "univglms2" categorical variables are allowed and hence this accepts data.frames. In this case, the categorical variables must be given as factor variables, otherwise you might get wrong results.
oiko	This can be either "normal", "poisson", "quasipoisson" or "binomial". If you are not sure leave it NULL and the function will check internally. However, you might have discrete data (e.g. years of age) and want to perform many simple linear regressions. In this case you should specify the family.
logged	A boolean variable; it will return the logarithm of the pvalue if set to TRUE.

Details

If you specify no family of distributions the function internally checkes the type of your data and decides on the type of regression to perform. The function is written in C++ and this is why it is very fast. It can accept thousands of predictor variables. It is usefull for univariate screening. We provide no p-value correction (such as fdr or q-values); this is up to the user.

Value

A matrix with the test statistic and the p-value for each predictor variable.

Author(s)

Michail Tsagris

R implementation and documentation: Michail Tsagris <mtsagris@uoc.gr> and Manos Papadakis <papadakm95@gmail.com>.

a2 <- glm(y ~ 1, binomial)$null.dev - a2
x <- NULL
```

`Many univariate simple linear regressions`
Many univariate simple linear regressions

Description

It performs very many univariate simple linear regressions with or without categorical variables.

Usage

```
regression(x, y, poia = NULL, logged = FALSE)
```

Arguments

`x`	A data.frame or a matrix with the data, where the rows denote the samples (and the two groups) and the columns are the variables. A data frame is expected if you have categorical predictor variables. If you only have continuous predictor variables you should the function `allbetas` instead as it is faster.
`y`	The dependent variable; a numerical vector.
`poia`	If the "x" is a data.frame and you know the indices of the columns which are categorical variables supply it here.
`logged`	Do you want the logarithm of the p-values be returned? The default value is FALSE.

Details

Some parts of the function will be transferred in C++. It can accept thousands of predictor variables. It is usefull for univariate screening. We provide no p-value correction (such as fdr or q-values); this is up to the user.

Value

A matrix with two columns, the test statistic value and its corresponding (logged) p-value.

Author(s)

```

Many univariate simple logistic and Poisson regressions

Many univariate simple binary logistic regressions

Description

It performs very many univariate simple binary logistic regressions.

Usage

```
logistic_only(x, y, tol = 1e-09, b_values = FALSE)
poisson_only(x, y, tol = 1e-09, b_values = FALSE)
```

Arguments

x	A matrix with the data, where the rows denote the samples (and the two groups) and the columns are the variables. Currently only continuous variables are allowed.
y	The dependent variable; a numerical vector with two values (0 and 1) for the logistic regressions and a vector with many discrete values (count data) for the Poisson regressions.
tol	The tolerance value to terminate the Newton-Raphson algorithm.
b_values	Do you want the values of the coefficients returned? If yes, set this to TRUE.

Details

The function is written in C++ and this is why it is very fast. It can accept thousands of predictor variables. It is usefull for univariate screening. We provide no p-value correction (such as fdr or q-values); this is up to the user.

Value

A vector with the deviance of each simple binayr logistic regression model for each predictor variable.

Author(s)

Manos Papadakis <papadakm95@gmail.com>

R implementation and documentation: Michail Tsagris <mtsagris@uoc.gr> and Manos Papadakis <papadakm95@gmail.com>.

Examples

```
## 300 variables, hence 300 univariate regressions are to be fitted
x <- matrix( rnorm(100 * 300), ncol = 300 )

## 100 observations in total
y <- rbinom(100, 1, 0.6)   ## binary logistic regression
a1 <- logistic_only(x, y)

a2 <- glm(y ~ x[, 1], binomial)$deviance
a2 <- as.vector(a2)

y <- rpois(100, 10)
a1 <- poisson_only(x, y)

a1 <- x <- NULL
```

`Many univariate simple quasi poisson regressions`
Many univariate simple poisson regressions

Description

It performs very many univariate simple poisson regressions.

Usage

```
quasi.poisson_only(x, y, tol = 1e-09, maxiters = 100)
```

Arguments

`x`	A matrix with the data, where the rows denote the samples (and the two groups) and the columns are the variables. Currently only continuous variables are allowed.
`y`	The dependent variable; a numerical vector with many discrete values (count data).
`maxiters`	The maximum number of iterations after which the Newton-Raphson algorithm is terminated.
`tol`	The tolerance value to terminate the Newton-Raphson algorithm.

Details

The function is written in C++ and this is why it is very fast. It can accept thousands of predictor variables. It is usefull for univariate screening. We provide no p-value correction (such as fdr or q-values); this is up to the user.

Value

A matrix with the deviance and the estimated phi parameter (dispersion parameter) of each simple poisson regression model for each predictor variable.

b1 <- poisson_only(x, y)
b2 <- quasi.poisson_only(x, y)

b1<-b2<-x<-y<-NULL
```

Many Welch's F-tests *Many Welch's F-tests*

Description

Many Welch's F-tests.

Usage

```
colanovas(y, x, logged = FALSE)
```

Arguments

y	A numerical vector with the dependent variable.
x	A matrix with the data, where the rows denote the samples (and the two groups) and the columns are the variables. This must be a matrix with the categorical variables as numbers, starting from 1. Welch's F-test is performed for each variable.
logged	A boolean variable; it will return the logarithm of the pvalue if set to TRUE.

Details

For each categorical variable in the x matrix Welch's F test is performed. This is the opposie of ftests, where there are many dependent variables and one categorical variable.

Value

A matrix with the test statistic and the p-value for each predictor variable.

Author(s)

Michail Tsagris

R implementation and documentation: Michail Tsagris <mtsagris@uoc.gr> and Manos Papadakis <papadakm95@gmail.com>.

regression, ftests, allbetas, correls

Examples

```
y <-  rnorm(100)
x <- matrix( rbinom(100 * 50, 2, 0.5) + 1 , ncol = 50)
a <- colanovas(y, x)
x <- NULL
```

Match *Match*

Description

Return the positions of its first argument that matches in its second.

Usage

```
Match(x,key=NULL)
```

Arguments

x	A numeric vector.
key	The value/vector for searching in vector x. For now let it NULL. **dont't use it!**.

Details

This function implements the R's \"match\" function. This version basicaly calculates the match(x,sort(unique(x))) for now. Do not use the argument key!

Value

Returns the position/positions of the given key/keys in the x vector.

Author(s)

Manos Papadakis

R implementation and documentation: Manos Papadakis <papadakm95@gmail.com>

See Also

match

Examples

```
y <- rnorm(100)
a <- Match(y)
b <-50
all.equal(as.vector(a),as.vector(b))
```

`Matrix multiplication` *Matrix multiplication, Cross and Tcross product.*

Description

Matrix multiplication, Cross and Tcross product.

Usage

```
mat.mult(x, y)
Crossprod(x,y)
Tcrossprod(x,y)
```

Arguments

x	A numerical matrix.
y	A numerical matrix.

Details

The functions performs matrix multiplication, croos product and transpose cross product. There are faster(!) than R's function for large matrices. Depending on the computer, maybe higher dimensions are required for the function to make a difference. The function runs in parallel in C++.

Value

A matrix, the result of the matrix multiplication.

Author(s)

Manos Papadakis

R implementation and documentation: Manos Papadakis <papadakm95@gmail.com>

b <- mat.mult(x, y)
b <- Crossprod(x, y)
b <- Tcrossprod(x, y)
x <- NULL
y <- NULL
b <- NULL
```

`Matrix with all pairs of t-tests`

Matrix with all pairs of t-tests

Description

Matrix with all pairs of t-tests.

Usage

```
allttests(x, y = NULL, ina, logged = FALSE)
ttests.pairs(x, logged = FALSE)
```

Arguments

`x`	A numerical matrix with the data.
`y`	For the case of "all.tests", if you have the second group or sample provide it here, otherwise leave it NULL. For the case of "ttests.pairs" this is not required.
`ina`	If you have the data in one matric then provide this indicator variable separating the samples. This numerical vector must contain 1s and 2s only as values. For the case of "ttests.pairs" this is not required.
`logged`	Should the p-values be returned (FALSE) or their logarithm (TRUE)?

Details

The function does all the pairwise t-tests assuming unequal variances (Welch's t-test). The "all.ttests" does all the pairs formed by "cutting" the matrices x and y in two and everything between them. The "ttests.pairs" accepts a matrix x and does all the pairs of t-tests. This is similar to the correlation matrix style.

Value

A list including:

`stat`	A matrix with t-test statistic for each pair of variables.
`pvalue`	A matrix with the corresponding p-values.
`dof`	A matrix with the relevant degrees of freedom.

Author(s)

Michail Tsagris

R implementation and documentation: Michail Tsagris <mtsagris@uoc.gr> and Manos Papadakis <papadakm95@gmail.com>.

`ttests`, `ftests`, `ttest`, `g2Test_univariate`

Examples

```
x <- as.matrix( iris[1:100, 1:4] )
ina <- as.numeric(iris[1:100, 5])
a <- allttests(x, ina = ina)
b <- ttests.pairs(x)  ## less tests
```

`Matrix with G-square tests of indepedence`

Matrix with G-square tests of indepdence

Description

Matrix with G-square tests of indepdence with and without permutations.

Usage

```
g2Test_univariate(data, dc)
g2Test_univariate_perm(data, dc, nperm)
chi2Test_univariate(data, dc)
```

Arguments

`data`	A numerical matrix with the data. **The minimum must be 0, otherwise the function can crash or will produce wrong results**. The data must be consecutive numbers.
`dc`	A numerical value equal to the number of variables (or columns of the data matrix) indicating the number of distinct, unique values (or levels) of each variable. Make sure you give the correct numbers here, otherwise the degrees of freedom will be wrong.

nperm The number of permutations. The permutations test is slower than without permutations and should be used with small sample sizes or when the contigency tables have zeros. When there are few variables, R's "chisq.test" function is faster, but as the number of variables increase the time difference with R's procedure becomes larger and larger.

Details

The function does all the pairwise G^2 test of independence and gives the position inside the matrix. The user must build the associations matrix now, similarly to the correlation matrix. See the examples of how to do that. The p-value is not returned, we live this to the user. See the examples of how to obtain it.

Value

A list including:

statistic	The G^2 or chi^2 test statistic for each pair of variables.
pvalue	This is returned when you have selected the permutation based G^2 test.
x	The row or variable of the data.
y	The column or variable of the data.
df	The degrees of freedom of each test.

Author(s)

Giorgos Borboudakis. The permutation version used a C++ code by John Burkardt.

```

`Mean - Median absolute deviation of a vector`

Mean - Median absolute deviation of a vector

Description

Mean - Median absolute deviation of a vector.

Usage

```
mad2(x,method = "median",na.rm=FALSE)
Mad(x,method = "median",na.rm=FALSE)
```

Arguments

`x`	A numerical vector.
`method`	A character vector with values "median", for median absolute deviation or "mean", for mean absolute deviation.
`na.rm`	A logical value TRUE/FALSE to remove NAs.

Value

The mean absolute deviation.

Author(s)

Michail Tsagris

R implementation and documentation: Michail Tsagris <mtsagris@uoc.gr>

See Also

Mad(x)
mad(x)
```

`Median of a vector` *Median of a vector*

Description

Median of a vector.

Usage

```
med(x,na.rm=FALSE)
Median(x,na.rm=FALSE)
```

Arguments

`x`	A numerical vector.
`na.rm`	TRUE or FAlSE for remove NAs if exists.

Details

The function is written in C++ and this is why it is very fast.

Value

The median of the vector of a numbers.

Author(s)

Manos Papadakis <papadakm95@gmail.com>

R implementation and documentation: Michail Tsagris <mtsagris@uoc.gr> and Manos Papadakis <papadakm95@gmail.com>.

`Minima and maxima of two vectors/matrices`
Minima and maxima of two vectors/matrices

Description

Minima and maxima of two vectors/matrices.

Usage

```
Pmax(x, y,na.rm = FALSE)
Pmin(x, y,na.rm = FALSE)
Pmin_Pmax(x, y,na.rm = FALSE)
```

Arguments

`x`	A numerical vector with numbers.
`y`	A numerical vector with numbers.
`na.rm`	TRUE or FAlSE for remove NAs if exists.

Details

The parallel minima or maxima are returned. This are the same as the base functions pmax and pmin.

Value

A numerical vector/matrix with numbers, whose length is equal to the length of the initial vectors/matrices containing the maximum or minimum between each pair.

Author(s)

Manos Papadakis

R implementation and documentation: Manos Papadakis <papadakm95@gmail.com>.

```
x <- rnorm(10)
y <- rnorm(10)
res<-Pmax(x, y)
a<-pmax(x, y)
res<-Pmin(x, y)
b<-pmin(x, y)
res<-Pmin_Pmax(x,y) == c(a,b)
a<-b<-x<-y<-NULL
```

Minimum and maximum *Minimum and maximum of a vector*

Description

Minimum and maximum of a vector.

Usage

```
min_max(x,index=FALSE, percent = FALSE)
```

Arguments

x	A numerical vector with data. NAs are handled naturally.
index	A boolean value for the indices of the minimum and the maximum value.
percent	A boolean value for the percent of the positive and negative numbers.

Value

A vector with the relevant values, min and max.

```

`Minimum and maximum frequencies` *Minimum and maximum frequencies of a vector*

Description

Minimum and maximum frequencies of a vector.

Usage

```
freq.min(x,na.rm = FALSE)
freq.max(x,na.rm = FALSE)
```

Arguments

`x`	A numerical/integer vector with data but without NAs.
`na.rm`	TRUE or FAlSE for remove NAs if exists.

Details

Those functions are the same with max(table(x) or min(table(x)) but with one exception. freq.min and freq.max will return also which value has the minimum/maximum frequency. More Efficient than max(table(x) or min(table(x)).

Value

A vector with 2 values, the value with minimum/maximum frequency and the frequency.

Author(s)

Manos Papadakis

R implementation and documentation: Manos Papadakis <papadakm95@gmail.com> and Marios Dimitriadis <kmdimitriadis@gmail.com>.

# f2r <- max(table(x))
# f1[2]==f1r ## the frequencies are the same
# f2[2]==f2r ## the frequencies are the same
```

`MLE for multivariate discrete data`

MLE for multivariate discrete data

Description

MLE for multivariate discrete data.

Usage

```
multinom.mle(x)
dirimultinom.mle(x, tol = 1e-07)
colpoisson.mle(x)
colgeom.mle(x, type = 1)
```

Arguments

`x`	A matrix with discrete valued non negative data.
`tol`	the tolerance level to terminate the Newton-Raphson algorithm for the Dirichlet multinomial distribution.
`type`	This is for the geometric distribution only. Type 1 refers to the case where the minimum is zero and type 2 for the case of the minimum being 1.

Details

For the Poisson and geometric distributions we simply fit independent Poisson and geometric distributions respectively.

Value

A list including:

`loglik`	A vector with the value of the maximised log-likelihood.
`param`	A vector of the parameters.

Author(s)

Michail Tsagris

R implementation and documentation: Michail Tsagris <mtsagris@uoc.gr> and Manos Papadakis <papadakm95@gmail.com>.

Examples

```
x <- t( rmultinom(1000, 20, c(0.4, 0.5, 0.1) ) )
res<-multinom.mle(x)
res<-colpoisson.mle(x)
x <- NULL
```

`MLE of (hyper-)spherical distributions`

MLE of (hyper-)spherical distributions

Description

MLE of (hyper-)spherical distributions.

Usage

```
vmf.mle(x, tol = 1e-07)
multivmf.mle(x, ina, tol = 1e-07, ell = FALSE)
acg.mle(x, tol = 1e-07)
iag.mle(x, tol = 1e-07)
```

Arguments

x	A matrix with directional data, i.e. unit vectors.
ina	A numerical vector with discrete numbers starting from 1, i.e. 1, 2, 3, 4,... or a factor variable. Each number denotes a sample or group. If you supply a continuous valued vector the function will obviously provide wrong results.
ell	This is for the multivmf.mle only. Do you want the log-likelihood returned? The default value is TRUE.
tol	The tolerance value at which to terminate the iterations.

Details

For the von Mises-Fisher, the normalised mean is the mean direction. For the concentration parameter, a Newton-Raphson is implemented. For the angular central Gaussian distribution there is a constraint on the estimated covariance matrix; its trace is equal to the number of variables. An iterative algorithm takes place and convergence is guaranteed. Newton-Raphson for the projected normal distribution, on the sphere, is implemented as well. Finally, the von Mises-Fisher distribution for groups of data is also implemented.

Value

For the von Mises-Fisher a list including:

`loglik`	The maximum log-likelihood value.
`mu`	The mean direction.
`kappa`	The concentration parameter.

For the multi von Mises-Fisher a list including:

`loglik`	A vector with the maximum log-likelihood values if ell is set to TRUE. Otherwise NULL is returned.
`mi`	A matrix with the group mean directions.
`ki`	A vector with the group concentration parameters.

For the angular central Gaussian a list including:

`iter`	The number if iterations required by the algorithm to converge to the solution.
`cova`	The estimated covariance matrix.

For the spherical projected normal a list including:

`iters`	The number of iteration required by the Newton-Raphson.
`mesi`	A matrix with two rows. The first row is the mean direction and the second is the mean vector. The first comes from the second by normalising to have unit length.
`param`	A vector with the elements, the norm of mean vector, the log-likelihood and the log-likelihood of the spherical uniform distribution. The third value helps in case you want to do a log-likleihood ratio test for uniformity.

MLE of continuous univariate distributions defined on the positive line

MLE of continuous univariate distributions defined on the positive line

---

Description

MLE of continuous univariate distributions defined on the positive line.

Usage

```
gammamle(x, tol = 1e-09)
chisq.mle(x, tol = 1e-09)
weibull.mle(x, tol = 1e-09, maxiters = 100)
lomax.mle(x, tol = 1e-09)
foldnorm.mle(x, tol = 1e-09)
betaprime.mle(x, tol = 1e-09)
logcauchy.mle(x, tol = 1e-09)
loglogistic.mle(x, tol = 1e-09)
halfnorm.mle(x)
invgauss.mle(x)
lognorm.mle(x)
pareto.mle(x)
expmle(x)
exp2.mle(x)
maxboltz.mle(x)
rayleigh.mle(x)
normlog.mle(x)
lindley.mle(x)
```

Arguments

x	A vector with positive valued data (zeros are not allowed).
tol	The tolerance level up to which the maximisation stops; set to 1e-09 by default.
maxiters	The maximum number of iterations the Newton-Raphson will perform.

Details

Instead of maximising the log-likelihood via a numerical optimiser we have used a Newton-Raphson algorithm which is faster. See wikipedia for the equations to be solved. For the t distribution we need the degrees of freedom and estimate the location and scatter parameters. If you want to to fit an inverse gamma distribution simply do "gamma.mle(1/x)". The log-likelihood and the parameters are for the inverse gamma.

The "normlog.mle" is simply the normal distribution where all values are positive. Note, this is not log-normal. It is the normal with a log link. Similarly to the inverse gaussian distribution where the mean is an exponentiated. This comes from the GLM theory.

Value

Usually a list with three elements, but this is not for all cases.

`iters`	The number of iterations required for the Newton-Raphson to converge.
`loglik`	The value of the maximised log-likelihood.
`param`	The vector of the parameters.

res<-normlog.mle(x)
```

`MLE of continuous univariate distributions defined on the real line`

MLE of continuous univariate distributions defined on the real line

---

Description

MLE of continuous univariate distributions defined on the real line.

Usage

```
normal.mle(x)
gumbel.mle(x, tol = 1e-09)
cauchy.mle(x, tol = 1e-09)
logistic.mle(x, tol = 1e-07)
ct.mle(x, tol = 1e-09)
tmle(x, v = 5, tol = 1e-08)
wigner.mle(x, tol = 1e-09)
laplace.mle(x)
```

Arguments

`x`	A numerical vector with data.
`v`	The degrees of freedom of the t distribution.
`tol`	The tolerance level up to which the maximisation stops set to 1e-09 by default.

Details

Instead of maximising the log-likelihood via a numerical optimiser we have used a Newton-Raphson algorithm which is faster. See wikipedia for the equation to be solved. For the t distribution we need the degrees of freedom and estimate the location and scatter parameters.

The Cauchy is the t distribution with 1 degree of freedom. If you want to fit such a distribution used the cauchy.mle and not the t.mle with 1 degree of freedom as it's faster. The Laplace distribution is also called double exponential distribution.

The wigner.mle refers to the wigner semicircle distribution.

Value

Usually a list with three elements, but this is not for all cases.

`iters`	The number of iterations required for the Newton-Raphson to converge.
`loglik`	The value of the maximised log-likelihood.
`param`	The vector of the parameters.

poisson.mle(x)
betageom.mle(x, tol = 1e-07)
betabinom.mle(x, N, tol = 1e-07)
```

Arguments

x	A vector with discrete valued data.
type	This argument is for the negative binomial and the geometric distribution. In the negative binomial you can choose which way your prefer. Type 1 is for smal sample sizes, whereas type 2 is for larger ones as is faster. For the geometric it is related to its two forms. Type 1 refers to the case where the minimum is zero and type 2 for the case of the minimum being 1.
N	This is for the binomial distribution only, specifying the total number of successes. If NULL, it is sestimated by the data. It can also be a vector of successes.
tol	The tolerance level up to which the maximisation stops set to 1e-09 by default.

Details

Instead of maximising the log-likelihood via a numerical optimiser we used a Newton-Raphson algorithm which is faster.

See wikipedia for the equation to be solved in the case of the zero inflated distribution. https://en.wikipedia.org/wiki/Zero-inflated_model. In order to avoid negative values we have used link functions, log for the $lambda$ and logit for the π as suggested by Lambert (1992). As for the zero truncated Poisson see https://en.wikipedia.org/wiki/Zero-truncated_Poisson_distribution.

zip.mle is for the zero inflated Poisson, whereas ztp.mle is for the zero truncated Poisson distribution.

Value

The following list is not inclusive of all cases. Different functions have different names. In general a list including:

mess	This is for the negbin.mle only. If there is no reason to use the negative binomial distribution a message will appear, otherwise this is NULL.
iters	The number of iterations required for the Newton-Raphson to converge.
loglik	The value of the maximised log-likelihood.
prob	The probability parameter of the distribution. In some distributions this argument might have a different name. For example, param in the zero inflated Poisson.

res<-poisson.mle(x)
res<-negbin.mle(x)
```

MLE of distributions defined in the (0, 1) interval

MLE of distributions defined in the (0, 1) interval

Description

MLE of distributions defined in the (0, 1) interval.

Usage

```
beta.mle(x, tol = 1e-09)
ibeta.mle(x, tol = 1e-09)
logitnorm.mle(x)
hsecant01.mle(x, tol = 1e-09)
```

Arguments

x	A numerical vector with proportions, i.e. numbers in (0, 1) (zeros and ones are not allowed).
tol	The tolerance level up to which the maximisation stops.

Details

Maximum likelihood estimation of the parameters of the beta distribution is performed via Newton-Raphson. The distributions and hence the functions does not accept zeros. "logitnorm.mle" fits the logistic normal, hence no nwewton-Raphson is required and the "hypersecant01.mle" uses the golden ratio search as is it faster than the Newton-Raphson (less calculations)

Value

A list including:

iters	The number of iterations required by the Newton-Raphson.
loglik	The value of the log-likelihood.
param	The estimated parameters. In the case of "hypersecant01.mle" this is called "theta" as there is only one parameter.

system.time( for(i in 1:1000) beta.mle(x) )
res<-beta.mle(x)
res<-ibeta.mle(x)

x <- runif(1000)
res<-hsecant01.mle(x)
res<-logitnorm.mle(x)
res<-ibeta.mle(x)

x <- rbeta(1000, 2, 5)
x[sample(1:1000, 50)] <- 0
res<-ibeta.mle(x)
```

MLE of some circular distributions
MLE of some circular distributions

Description

MLE of some circular distributions.

Usage

```
vm.mle(x, tol = 1e-09)
spml.mle(x, tol = 1e-09, maxiters = 100)
wrapcauchy.mle(x, tol = 1e-09)
```

Arguments

x	A numerical vector with the circular data. They must be expressed in radians. For the "spml.mle" this can also be a matrix with two columns, the cosinus and the sinus of the circular data.
tol	The tolerance level to stop the iterative process of finding the MLEs.
maxiters	The maximum number of iterations to implement.

Details

The parameters of the von Mises, the bivariate angular Gaussian and wrapped Cauchy distributions are estimated. For the Wrapped Cauchy, the iterative procedure described by Kent and Tyler (1988) is used. As for the von Mises distribution, we use a Newton-Raphson to estimate the concentration parameter. The angular Gaussian is described, in the regression setting in Presnell et al. (1998).

Value

A list including:

iters	The iterations required until convergence. This is returned in the wrapped Cauchy distribution only.
loglik	The value of the maximised log-likelihood.
param	A vector consisting of the estimates of the two parameters, the mean direction for both distributions and the concentration parameter kappa and the rho for the von Mises and wrapped Cauchy respectively.
gamma	The norm of the mean vector of the angualr Gaussian distribution.
mu	The mean vector of the angular Gaussian distribution.

`MLE of the inverted Dirichlet distribution`

MLE of the inverted Dirichlet distribution

Description

MLE of the inverted Dirichlet distribution.

Usage

```
invdir.mle(x, tol = 1e-07)
```

Arguments

`x`	A matrix with strictly positive data (no zeros are allowed).
`tol`	The tolerance level up to which the maximisation stops.

Details

Maximum likelihood estimation of the parameters of the inverted is performed via Newton-Raphson. We took the initial values suggested by Bdiri T. and Bouguila N. (2012) and modified them a bit.

Value

A list including:

`iters`	The number of iterations required by the Newton Raphson.
`loglik`	The value of the log-likelihood.
`param`	The estimated parameters.

`MLE of the multivariate (log-) normal distribution`

MLE of the multivariate (log-) normal distribution

Description

MLE of the multivariate (log-) normal distribution.

Usage

```
mvnorm.mle(x)
mvlnorm.mle(x)
```

Arguments

`x`	A matrix with numerical data.

Details

The mean vector, covariance matrix and the value of the log-likelihood of the multivariate normal or log-normal distribution is calculated. For the log-normal distribution we also provide the expected value and the covariance matrix.

Value

A list including:

`loglik`	The log-likelihood multivariate distribution.
`mu`	The mean vector.
`sigma`	The covariance matrix.
`m`	The expected mean vector of the multivariate log-normal distribution.
`s`	The expected covariance matrix of the multivariate log-normal distribution.

MLE of the multivariate t distribution

Description

MLE of the multivariate t distribution.

Usage

```
mvt.mle(x, v = 5, tol = 1e-07)
```

Arguments

`x`	A matrix with numerical data.
`v`	The degrees of freedom. Must be a positive number, greater than zero.
`tol`	The tolerance value to terminate the EM algorithm.

Details

The location vector, scatter matrix and the value of the log-likelihood is calculated.

Value

A list including:

`iters`	The number of iterations required for the EM algorihm to converge.
`loglik`	The value of the maximised log-likelihood.
`location`	The location vector.
`scatter`	The scatter matrix.

`MLE of the ordinal model without covariates`

MLE of the ordinal model without covariates

Description

MLE of the ordinal model without covariates.

Usage

```
ordinal.mle(y, link = "logit")
```

Arguments

`y`	A numerical vector with values 1, 2, 3,..., not zeros, or an ordered factor.
`link`	This can either be "logit" or "probit". It is the link function to be used.

Details

Maximum likelihood of the ordinal model (proportional odds) is implemented. See for example the "polr" command in R or the examples.

Value

A list including:

`loglik`	The log-likelihood of the model.
`a`	The intercepts (threshold coefficients) of the model.

```

MLE of the tobit model

MLE of the tobit model

Description

MLE of the tobit model.

Usage

```
tobit.mle(y, tol = 1e-09)
```

Arguments

y	A vector with positive valued data and zero values. If there are no zero values, a simple normal model is fitted in the end.
tol	The tolerance level up to which the maximisation stops; set to 1e-09 by default.

Details

The tobin model is useful for (univariate) positive data with left censoring at zero. There is the assumption of a latent variable. Tthe values of that variable which are positive concide with the observed values. If some values are negative, they are left censored and the observed values are zero. Instead of maximising the log-likelihood via a numerical optimiser we have used a Newton-Raphson algorithm which is faster.

Value

A list with three elements including

iters	The number of iterations required for the Newton-Raphson to converge.
loglik	The value of the maximised log-likelihood.
param	The vector of the parameters.

```

`Moment and maximum likelihood estimation of variance components`
Moment and maximum likelihood estimation of variance components

---

Description

Moment and maximum likelihood estimation of variance components.

Usage

```
rint.mle(x, ina, ranef = FALSE, tol = 1e-09, maxiters = 100)
varcomps.mom(x, ina)
varcomps.mle(x, ina, tol = 1e-09)
```

Arguments

x	A numerical vector with the data.
ranef	Should the random effects be returned as well? The default value is FALSE.
ina	A numerical vector with 1s, 2s, 3s and so one indicating the two groups. Be careful, the function is desinged to accept numbers greater than zero. Alternatively it can be a factor variable.
tol	The tolerance level to terminate the golden ratio search. the default value is 10^(-9).
maxiters	The maximum number of iterations Newton-Raphson will implement.

Details

Note that the "varcomps.mle" and "varcomp.mom" work for **balanced designs only**, i.e. for each subject the same number of measurements have been taken. The "rint.mle" works for both the balanced and unbalanced designs.

The variance components, the variance of the between measurements and the variance of the within are estimated using moment estimators. The "colvarcomsp.mom" is the moment analogue of a random effects model which uses likelihood estimation ("colvarcomps.mle"). It is much faster, but can give negative variance of the random effects, in which case it becomes zero.

The maximum likelihood version is a bit slower (try youselves to see the difference), but statistically speaking is to be preferred when small samples are available. The reason why it is only a little bit slower and not a lot slower as one would imagine is because we are using a closed formula to calculate the two variance components (Demidenko, 2013, pg. 67-69). Yes, there are closed formulas for linear mixed models.

Value

For the "varcomps.mom": A vector with 5 elemets, The MSE, the estimate of the between variance, the variance components ratio and a 95% confidence for the ratio.

For the "varcomps.mle": a list with a single component called "info". That is a matrix with 3 columns, The MSE, the estimate of the between variance and the log-likelihood value. **If ranef = TRUE** a list including "info" and an extra component called "ranef" containing the random effects. It is a matrix with the same number of columns as the data. Each column contains the randome effects of each variable.

x <- c(98,97,99,96,91,90,93,92,96,95,97,95,95,96,99,98)
ina <- rep(1:4, each = 4)
res<-varcomps.mom(x, ina)
res<-varcomps.mle(x, ina)
```

`Multi-sample tests for vectors`

Multi-sample tests for vectors

Description

Multi-sample tests for vectors.

Usage

```
ftest(x, ina, logged = FALSE)
anova1(x, ina, logged = FALSE)
kruskaltest(x, ina, logged = FALSE)
var2test(x, y, alternative = "unequal", logged = FALSE)
mcnemar(x, y, logged = FALSE)
ttest2(x, y, paired = FALSE, logged = FALSE)
cqtest(x, treat, block, logged = FALSE)
block.anova(x, treat, block, logged = FALSE)
twoway.anova(y, x1, x2, interact = FALSE, logged = FALSE)
```

Arguments

`x`	A numerical vector with the data.
`y`	A numerical vector with the data.
`ina`	A numerical vector with 1s, 2s, 3s and so one indicating the two groups. Be careful, the function is desinged to accept numbers greater than zero. Alternatively it can be a factor variable.
`paired`	This is for the two sample t-test only and is TRUE or FALSE specifying whether the two samples are paired or not.
`alternative`	This can either be "unequal", "greater" or "less".
`treat`	In the case of the blocking ANOVA and Cochran's Q test, this argument plays the role of the "ina" argument.
`block`	This item (in the blocking ANOVA and Cochran's Q test) denotes the subjects which are the same. Similarly to "ina" a numeric vector with 1s, 2s, 3s and so on.
`x1`	The first factor in the two way ANOVA.
`x2`	The second factor in the two way ANOVA. The orderis not important.
`interact`	Should interaction in the two way ANOVA be included? The default value is FALSE (no interaction).
`logged`	Should the p-values be returned (FALSE) or their logarithm (TRUE)?

Details

The Welch's F-test (without assuming equal variances) is performed with the "ftest" function. The "anova" function perform the classical (Fisher's) one-way analysis of variance (ANOVA) which assumes equal variance across the groups. The "kruskaltest" performs the Kruskal-Wallis non parametric alternative to analysis of variance test. The "var2tests" implement the classical F test for the equality of two sample variances. The "cqtest" performs the Cocrhan's Q test for the equality of more than two groups whose values are strictly binary (0 or 1). This is a generalisation of the McNemar's test in the multi-sample case. The "block.anova" is the ANOVA with blocking, randomised complete block design (RCBD). In this case, for every combination of the block and treatment values, there is only one observation. The mathematics are the same as in the case of "twoway.anova", but the assumptions different and the testing procedure also different. In addition, no interaction is present.

Value

A vector with the test statistic and the p-value of each test. For the case of t-test, an extra column with the degrees of freedom is given. For the two way ANOVA there can can be either 2 or three F test statistics and hence the same number of p-values.

`Multinomial regression` *Multinomial regression*

Description

Multinomial regression.

Usage

```
multinom.reg(y, x, tol = 1e-07, maxiters = 50)
```

Arguments

`y`	The response variable. A numerical or a factor type vector.
`x`	A matrix or a data.frame with the predictor variables.
`tol`	This tolerance value to terminate the Newton-Raphson algorithm.
`maxiters`	The maximum number of iterations Newton-Raphson will perform.

Value

A list including:

`iters`	The number of iterations required by the Newton-Raphson.
`loglik`	The value of the maximised log-likelihood.
`be`	A matrix with the estimated regression coefficients.

`Multivariate Laplace random values simulation`
Multivariate Laplace random values simulation

Description

Multivariate Laplace random values simulation.

Usage

```
rmvlaplace(n, lam, mu, G, seed = NULL)
```

Arguments

`n`	The sample size, a numerical value.
`lam`	The the parameter of the exponential distribution, a positive number.
`mu`	The mean vector.
`G`	A $d \times d$ covariance matrix with determinant 1.
`seed`	If you want the same to be generated again use a seed for the generator, an integer number.

Details

The algorithm uses univariate normal random values and transforms them to multivariate via a spectral decomposition.

Value

A matrix with the simulated data.

Author(s)

Michail Tsagris

R implementation and documentation: Michail Tsagris <mtsagris@uoc.gr>

x <- rmvlaplace(100, lam, m, s)
```

`Multivariate normal and t random values simulation`

Multivariate normal and t random values simulation

Description

Multivariate normal and t random values simulation.

Usage

```
rmvnorm(n, mu, sigma, seed = NULL)
rmvt(n, mu, sigma, v, seed = NULL)
```

Arguments

`n`	The sample size, a numerical value.
`mu`	The mean vector in R^d.
`sigma`	The covariance matrix in R^d.
`v`	The degrees of freedom.
`seed`	If you want the same to be generated again use a seed for the generator, an integer number.

Details

The algorithm uses univariate normal random values and transforms them to multivariate via a spectral decomposition. It is faster than the command "mvrnorm" available from MASS, and it allows for singular covariance matrices.

Value

A matrix with the simulated data.

Author(s)

Michail Tsagris

R implementation and documentation: Michail Tsagris <mtsagris@uoc.gr>

res<-colmeans(y)
res<-cov(y)
y <- NULL
```

Naive Bayes classifiers

Naive Bayes classifiers

Description

Gaussian, Poisson, geometric and multinomial naive Bayes classifiers.

Usage

```
gaussian.nb(xnew = NULL, x, ina, parallel = FALSE)
poisson.nb(xnew, x, ina)
multinom.nb(xnew, x, ina)
geom.nb(xnew, x, ina, type = 1)
gammanb(xnew = NULL, x, ina, tol = 1e-07)
```

Arguments

xnew	A numerical matrix with new predictor variables whose group is to be predicted. For the Gaussian naive Bayes, this is set to NUUL, as you might want just the model and not to predict the membership of new observations. For the Gaussian case this contains any numbers, but for the multinomial and Poisson cases, the matrix must contain integer valued numbers only.
x	A numerical matrix with the observed predictor variable values. For the Gaussian case this contains any numbers, but for the multinomial and Poisson cases, the matrix must contain integer valued numbers only.
ina	A numerical vector with strictly positive numbers, i.e. 1,2,3 indicating the groups of the dataset. Alternatively this can be a factor variable.
type	Type 1 refers to the case where the minimum is zero and type 2 for the case of the minimum being 1. This is for the geometric distribution. This argument is for the geometric distribution. Type 1 refers to the case where the minimum is zero and type 2 for the case of the minimum being 1.
tol	The tolerance value to terminate the Newton-Raphson algorithm in the gamma distribution.
parallel	If you want parallel computations set this equal to TRUE.

Value

For the Poisson and Multinomial naive Bayes classifiers the estimated group, a numerical vector with 1, 2, 3 and so on. For the Gaussian naive Bayes classifier a list including:

`mu`	A matrix with the mean vector of each group based on the dataset.
`sigma`	A matrix with the variance of each group and variable based on the dataset.
`ni`	The sample size of each group in the dataset.
`est`	The estimated group of the xnew observations. It returns a numerical value back regardless of the target variable being numerical as well or factor. Hence, it is suggested that you do \"as.numeric(target)\" in order to see what is the predicted class of the new data.

For the Gamma classifier a list including:

`a`	A matrix with the shape parameters.
`b`	A matrix with the scale parameters.
`est`	The estimated group of the xnew observations. It returns a numerical value back regardless of the target variable being numerical as well or factor. Hence, it is suggested that you do \"as.numeric(target)\" in order to see what is the predicted class of the new data.

```

`Natural Logarithm each element of a matrix`
Natural Logarithm each element of a matrix

Description

Natural Logarithm each element of a matrix.

Usage

```
Log(x, na.rm = FALSE)
```

Arguments

`x`	A matrix with data.
`na.rm`	A boolean value (TRUE/FALSE) for removing NA.

Details

The argument must be a matrix. For vector the time was the same as R's "log" function so we did not add it.

Value

A matrix where each element is the natural logarithm of the given argument.

Author(s)

Manos Papadakis

R implementation and documentation: Manos Papadakis <papadakm95@gmail.com>.

x <-matrix( runif( 100 * 100), ncol = 100 )
a <- log(x)
b <- Log(x)
all.equal(a, b) # true

x<-a<-b<-NULL
```

Natural logarithm of the beta function

Natural logarithm of the beta function

Description

Natural logarithm of the beta function.

Usage

```
Lbeta(x, y)
```

Arguments

x	A numerical matrix, or a vector or just a number with positive numbers in either case.
y	A numerical matrix, or a vector or just a number with positive numbers in either case. The dimensions of y must match those of x.

Details

The function is faster than R's lbeta when the dimensions of x any are large. If you have only two numbers, then lbeta is faster. But if you have for example two vectors of 1000 values each, Lbeta becomes two times faster than lbeta.

Value

The matrix, vector or number with the resulting values.

Author(s)

Manos Papadakis

R implementation and documentation: Manos Papadakis <papadakm95@gmail.com>.

y <- rexp(1000)
a1 <- Lbeta(x, y)

x<-y<-a1<-NULL
```

`Natural logarithm of the gamma function and its derivatives`
Natural logarithm of the gamma function and its derivatives.

Description

Natural logarithm of the gamma function and its derivatives.

Usage

```
Lgamma(x)
Digamma(x)
Trigamma(x)
```

Arguments

x	A numerical matrix or vector with positive numbers in either case.

Details

We have spotted that the time savings come when there are more than 50 elements, with vector or matrix.

Value

The matrix or the vector with the resulting values.

Author(s)

Manos Papadakis

R implementation and documentation: Manos Papadakis <papadakm95@gmail.com>.

all.equal(as.vector(a1), as.vector(a2))

a1 <- Digamma(x)
a2 <- digamma(x)
all.equal(as.vector(a1), as.vector(a2))

x<-a1<-a2<-NULL
```

Norm of a matrix *Norm of a matrix*

Description

Norm of a matrix.

Usage

```
Norm(x, type = "F")
```

Arguments

x	A matrix with numbers.
type	The type of norm to be calculated. The default is "F" standing for Frobenius norm ("f" in R's norm). The other options are "C" standing for the one norm ("o" in R's norm), "R" for the identiy norm ("I" in R's norm) and "M" for the maximum modulus among elements of a matrix ("M" in R's norm)

Value

A number, the norm of the matrix.

Author(s)

Manos Papadakis

R implementation and documentation: Manos Papadakis <papadakm95@gmail.com>.

res<-norm(x, "M")
```

`Number of equal columns between two matrices`
Number of equal columns between two matrices

Description

Number of equal columns between two matrices.

Usage

```
mat.mat(x, y)
```

Arguments

x	A numerical matrix. See details for more information. It must have the same number of rows as y.
y	A numerical matrix. See details for more information. It must have the same number of rows as x.

Details

The function takes each column of x and checks the number of times it matches a column of y. In the example below, we take the first 3 columns of iris as the x matrix. The y matrix is the whole of iris. We will see how many times, each column of x appears in the y matrix. The answer is 1 for each column.

Value

A numerical vector of size equal to the number of columns of x.

x<-y<-NULL
```

`Odds ratio and relative risk`

Odds ratio and relative risk

Description

Odds ratio and relative risk.

Usage

```
odds.ratio(x, a = 0.05, logged = FALSE)
rel.risk(x, a = 0.05, logged = FALSE)
```

Arguments

`x`	A 2 x 2 matrix or a vector with 4 elements. In the case of the vector make sure it corresponds to the correct table.
`a`	The significance level, set to 0.05 by default.
`logged`	Should the p-values be returned (FALSE) or their logarithm (TRUE)?

Details

The odds ratio and the confidence interval are calculated.

Value

A list including:

`res`	The estimated odds ratio and the p-value for the null hypothesis test that it is equal to 1.
`ci`	The (1-a)% confidence interval for the true value of the odds ratio.

Author(s)

Michail Tsagris

R implementation and documentation: Michail Tsagris <mtsagris@uoc.gr>.

`One sample t-test for a vector`

One sample t-test for a vector

Description

One sample t-test for a vector.

Usage

```
ttest1(x, m, alternative = "unequal", logged = FALSE, conf = NULL)
```

Arguments

`x`	A numerical vector with the data.
`m`	The mean value under the null hypothesis.
`alternative`	The alternative hypothesis, "unequal", "greater" or "less".
`logged`	Should the p-values be returned (FALSE) or their logarithm (TRUE)?
`conf`	If you want a confidence interval supply the confidence level.

Details

The usual one sample t-test is implemented, only faster.

Value

A list including:

`res`	A two valued vector with the test statistic and its (logged) p-value.
`ci`	In the case you supplied a number in the input argument "conf" the relevant confidence interval will be returned as well.

Operations between two matrices or matrix and vector

Operations between two matrices or matrix and vector

Description

Operations between two matrices or matrix and vector.

Usage

```
XopY.sum(x, y = NULL, oper = "*")
eachrow(x,y,oper = "*",method = NULL)
eachcol.apply(x,y,indices = NULL,oper = "*",apply = "sum")
```

Arguments

x	A numerical matrix.
y	A second numerical matrix for "XopY.sum" whose dimensions must match the ones of x, or vector for "eachrow","eachcol.apply" whose length must match with the rows of x.
oper	The operation to be performed, either "*", "/", "+", "-" or "==".
method	A character value for choosing option to apply in the result. Options: 1) sum 2) max 3) min Does not work for oper="==".
indices	An integer vector with indices to specific columns. Only for "eachcol.apply".
apply	A character value with the function to be applied in the columns of the matrix. Only for "eachcol.apply". Options: 1) sum 2) median 3) max 4) min

Details

XopY.sum: sum(X op Y) where op can be on of "+,-,*,/".

eachrow: X op Y **by row** or **FUNCTION**(X op Y) where "x" is matrix, "y" is vector with length as much an the columns of x and "op" is one of "+,-,*,/,==", and "FUNCTION" is a specific method for applying in the result matrix (see argument method).

eachcol.apply: **FUNCTION**(X op Y) **by column** where "x" is matrix, "y" is vector with length as much an the rows of x, "op" is one of "+,-,*,/" and "FUNCTION" is a specific method (see argument apply).

NOTE: Arguments "method" does not work for oper="==" and this operation works only in "eachrow".

Value

XopY.sum: sum(X op Y) where "op" can be on of "+,-,*,/".

eachrow: operation by row between a matrix and a vector."op" can be on of "+,-,*,/". If "suma=TRUE" then returns the sum of this operation.

eachcol.apply: operation by column between a matrix and a vector and applied a specific function."op" can be on of "+,-,*,/".

Examples

```
x <- matrix( rnorm(5 * 5), ncol = 5 )
y <- matrix( rnorm(5 * 5), ncol = 5 )
res<-XopY.sum(x, y, oper = "*")
y <- x[,1]
res<-eachrow(x,y)

all.equal(eachcol.apply(x,y),colsums(x*y))

x<-y<-NULL
```

Orthogonal matching pursuit variable selection

Orthogonal matching pursuit variable selection

Description

Orthogonal matching pursuit variable selection.

Usage

```
ompr(y, x, ystand = TRUE, xstand = TRUE, method = "BIC", tol = 2 )
omp(y, x, xstand = TRUE, tol = qchisq(0.95, 1) + log( length(y) ), type = "logistic" )
```

Arguments

y	The response variable, a numeric vector. For "ompr" this is a continuous variable. For "omp" this can be either a vector with discrete (count) data, 0 and 1, non negative values, strictly positive or proportions including 0 and 1.
x	A matrix with the data, where the rows denote the observations and the columns are the variables.
ystand	If this is TRUE the response variable is centered. The mean is subtracted from every value.
xstand	If this is TRUE the independent variables are standardised.
method	You can choose between the change in the BIC ("BIC"), the adjusted R^2 ("ar2"), the SSE ("SSE") or the classical p-value based ("pvalue").
tol	The tolerance value to terminate the algorithm. This is the change in the criterion value between two successive steps. For "ompr" the default value is 2 because the default method is "BIC". For "omp" the default value is the 95% quantile of the χ^2 distribution with 1 degree of freedom plus the logarithm of the sample size.
type	This denotes the parametric model to be used each time. It depends upon the nature of y. The possible values are "logistic", "poisson", "quasipoisson", "quasibinomial", "normlog", "gamma", "weibull", "mv" (for multivariate response variable) or "multinomial".

Value

For "ompr" a list including:

runtime	The runtime of the algorithm.
info	A matrix with two columns. The selected variable(s) and the criterion value at every step.

For "omp" a list including:

runtime	The runtime of the algorithm.

`phi` The ϕ parameter. In the cases of "quasipoisson", "quasibinomial" and "normlog" this is useful. For all other cases this is NULL.

`info` A matrix with two columns. The selected variable(s) and the criterion value at every step.

Author(s)

a
x <- NULL
```

`Outer function` *Outer function*

Description

The outer function.

Usage

```
Outer(x, y, oper = "*")
```

Arguments

x	A numerical vector.
y	A numerical vector.
oper	The available options are "*" (multiplication), "/" (division), "+" (sum), "-" (substraction), "^" (power raise), and "

Details

The function is the same as R's "outer", but works with vectors only and probably has less capabilities, but faster.

Value

A matrix with all the combinations.

Author(s)

Manos Papadakis and Michail Tsagris

R implementation and documentation: Manos Papadakis <papadakm95@gmail.com> and Michail Tsagris <mtsagris@uoc.gr>.

See Also

x <- rnorm(10)
y <- rnorm(10)
res<-Outer(x, y)
```

Permutation *Permutation*

Description

Permute the given vector.

Usage

```
permutation(x, nperm = gamma(length(x)+1))
permutation.next(x, nperm = gamma(length(x)+1))
permutation.prev(x, nperm = gamma(length(x)+1))
bincomb(n)
```

Arguments

x	A numeric vector with data.
nperm	An integer value for returning specific number of combinations. By defualt is set to all combinations. Must be between **0<=nperm<=gamma(length(x)+1)**
n	An integer value for the length of the binary number.

Details

This function implements "Permutation", which means all the possible combinations. In the permutation.next and permutation.prev if there aren't possible combinations it returns the same vector. "Binary Combinations" for "bincomb", means all the possible combinations for the binary number with length "n".

Value

Returns a matrix with all possible combinations of the given vector or a matrix row with one possible combinations.

Permutation based p-value for the Pearson correlation coefficient

Permutation based p-value for the Pearson correlation coefficient

---

Description

Permutation based p-value for the Pearson correlation coefficient.

Usage

```
permcor(x, y, R = 999)
```

Arguments

x	A numerical vector with the first variable.
y	A numerical vector with the second variable.
R	The number of permutations to be conducted; set to 999 by default.

Details

This is a very low computational calculation of the p-value. Try it yourselves.

Value

A vector consisting of two values, the Pearson correlation and the permutation based p-value.

`Polyserial correlation`

Polyserial correlation

Description

Polyserial correlation.

Usage

```
poly.cor(x, y)
```

Arguments

x	The continuous variable.
y	The ordinal variable, a numeric vector with numbers starting from 1.

Details

The polyserial correlation between a continuous and an ordinal variable is calculated. The function is not super fast, yet is faster than other implementations we found.

Value

A list including:

est	A vector with the polyserial correlation and its estimated variance.
test	A vector with the test statistic and its associated p-value.

Author(s)

Michail Tsagris

R implementation and documentation: Michail Tsagris <mtsagris@uoc.gr>

References

```

Pooled covariance matrix

Pooled covariance matrix

Description

Pooled covariance matrix.

Usage

```
pooled.cov(x, ina)
```

Arguments

x	A matrix with continuous data.
ina	A numerical vector indicating the groups. **The nubmers must be consecutive and start from 1**.

Details

The spatial median is at first computed (if not supplied) and then the covariance matrix.

Value

The spatial sign covariance matrix.

Author(s)

Michail Tsagris

R implementation and documentation: Michail Tsagris <mtsagris@uoc.gr>.

References

Durre A, Vogel D. and D.E. Tyler D.E.(2014). The spatial sign covariance matrix with unknown location. Journal of Multivariate Analysis, 130: 107-117. http://arxiv.org/pdf/1307.5706v2.pdf

```

`Prediction with some naive Bayes classifiers`
Prediction with some naive Bayes classifiers

Description

Prediction with some naive Bayes classifiers.

Usage

```
gaussiannb.pred(xnew, m, s, ni)
poissonnb.pred(xnew, m)
multinomnb.pred(xnew, m)
gammanb.pred(xnew, a, b)
geomnb.pred(xnew, prob)
```

Arguments

`xnew`	A numerical matrix with new predictor variables whose group is to be predicted. For the Gaussian case this contains any numbers, but for the multinomial and Poisson cases, the matrix must contain integer valued numbers only.
`m`	A matrix with the group means. Each row corresponds to a group.
`s`	A matrix with the group colum-wise variances. Each row corresponds to a group.
`ni`	A vector with the frequencies of each group.
`a`	A vector with the shape parameters of each group.
`b`	A vector with the scale parameters of each group.
`prob`	A vector with the sprobability parameters of each group.

Value

A numerical vector with 1, 2, ... denoting the predicted group.

Author(s)

Michail Tsagris

R implementation and documentation: Michail Tsagris <mtsagris@uoc.gr> and Manos Papadakis <papadakm95@gmail.com>.

`gaussian.nb`, `colpoisson.mle` `colVars`

Examples

```
ina <- sample(1:150, 100)
x <- as.matrix(iris[, 1:4])
id <- as.numeric(iris[, 5])
a <- gaussian.nb(xnew = NULL, x[ina, ], id[ina])
est <- gaussiannb.pred(x[-ina, ], a$mu, a$sigma, a$ni)
res<-table(id[-ina], est)
```

Quasi binomial regression for proportions

Quasi binomial regression for proportions

Description

Quasi binomial regression for proportions.

Usage

```
prop.reg(y, x, varb = "quasi", tol = 1e-09, maxiters = 100)
prop.regs(y, x, varb = "quasi", tol = 1e-09, logged = FALSE, maxiters = 100)
```

Arguments

y	A numerical vector proportions. 0s and 1s are allowed.
x	For the "prop.reg" a matrix with data, the predictor variables. This can be a matrix or a data frame. For the "prop.regs" this must be a numerical matrix, where each columns denotes a variable.
tol	The tolerance value to terminate the Newton-Raphson algorithm. This is set to 10^{-9} by default.
varb	The type of estimate to be used in order to estimate the covariance matrix of the regression coefficients. There are two options, either "quasi" (default value) or "glm". See the references for more information.
logged	Should the p-values be returned (FALSE) or their logarithm (TRUE)?
maxiters	The maximum number of iterations before the Newton-Raphson is terminated automatically.

Details

We are using the Newton-Raphson, but unlike R's built-in function "glm" we do no checks and no extra calculations, or whatever. Simply the model. The "prop.regs" is to be used for very many univariate regressions. The "x" is a matrix in this case and the significance of each variable (column of the matrix) is tested. The function accepts binary responses as well (0 or 1).

Value

For the "prop.reg" function a list including:

`iters`	The number of iterations required by the Newton-Raphson.
`varb`	The covariance matrix of the regression coefficients.
`phi`	The phi parameter is returned if the input argument "varb" was set to "glm", othwerise this is NULL.
`info`	A table similar to the one produced by "glm" with the estimated regression coefficients, their standard error, Wald test statistic and p-values.

For the "prop.regs" a two-column matrix with the test statistics (Wald statistic) and the associated p-values (or their loggarithm).

Author(s)

Michail Tsagris

R implementation and documentation: Michail Tsagris <mtsagris@uoc.gr> and Manos Papadakis <papadakm95@gmail.com>.

Examples

```
y <- rbeta(100, 1, 4)
x <- matrix(rnorm(100 * 3), ncol = 3)
a <- prop.reg(y, x)
y <- rbeta(100, 1, 4)
x <- matrix(rnorm(400 * 100), ncol = 400)
b <- prop.regs(y, x)
res<-mean(b[, 2] < 0.05)
```

Quasi Poisson regression for count data

Quasi Poisson regression

Description

Quasi Poisson regression.

Usage

```
qpois.reg(x, y, full = FALSE, tol = 1e-09,maxiters = 100)
qpois.regs(x, y, tol = 1e-09, logged = FALSE)
```

Arguments

x	For the "qpois.reg" a matrix with data, the predictor variables. This can be a matrix or a data frame. For the "qpois.regs" this must be a numerical matrix, where each columns denotes a variable.
y	A numerical vector with positive discrete data.
full	If this is FALSE, the coefficients, the deviance and the estimated phi parameter will be returned only. If this is TRUE, more information is returned.
tol	The tolerance value to terminate the Newton-Raphson algorithm. This is set to 10^{-9} by default.
logged	Should the p-values be returned (FALSE) or their logarithm (TRUE)?
maxiters	The maximum number of iterations before the Newton-Raphson is terminated automatically.

Details

We are using the Newton-Raphson, but unlike R's built-in function "glm" we do no checks and no extra calculations, or whatever. Simply the model, unless the user requests for the Wald tests of the coefficients. The "qpois.regs" is to be used for very many univariate regressions. The "x" is a matrix in this case and the significance of each variable (column of the matrix) is tested.

Value

For the "prop.reg" a list including: When full is FALSE

be	The regression coefficients.
devi	The deviance of the model.
varb	The covariance matrix of the beta coefficients.
phi	The phi parameter, the estimate of dispersion.

When full is TRUE, the additional item is:

`info` The regression coefficients, their standard error, their Wald test statistic and their p-value.

For the "prop.regs" a two-column matrix with the test statistics (Wald statistic) and the associated p-values (or their loggarithm).

res<-qpois.reg(x, y, full = TRUE)
res<-qpois.regs(x, y)
```

`Random intercepts linear mixed models`

Random intercepts linear mixed models

Description

Random intercepts linear mixed models (for balanced data with a single identical covariate).

Usage

```
rint.reg(y, x, id ,tol = 1e-08, ranef = FALSE, maxiters = 100)
rint.regbx(y, x, id)
```

Arguments

y	A numerical vector with the data. The subject values.
x	For the case of "rint.reg" this can be a vector or a numerical matrix with data. In the case of "rint.regbx" this is a numerical vector with the same length as y indicating the fixed predictor variable. Its values are the same for all levels of y. An example of this x is time which is the same for all subjects.
id	A numerical variable with 1, 2, ... indicating the subject.
tol	The tolerance level to terminate the generalised elast squares algorithm.
ranef	If you want to obtain the random effects (random intercepts) set this equal to TRUE.
maxiters	The max number of iterations that can take place in a regression.

Details

Random intercepts linear mixed models with compound covariance structure is fitted in both functions. The "rint.reg" allows any numerical matrix, with balanced or unbalanced data. See Demidenko (2013, pg. 65-67) for more information.

The "rint.regbx" is a special case of a balanced random intercepts model with a compound symmetric covariance matrix and one single covariate which is constant for all replicates. An example, is time, which is the same for all subjects. Maximum likelihood estimation has been performed. In this case the mathematics exist in a closed formula (Demidenko, 2013, pg. 67-69).

Value

A list including:

info	A vector with the random intercepts variance (between), the variance of the errors (within), the log-likelihood, the deviance (twice the log-likelihood) and the BIC. In the case of "rint.reg" it also includes the number of iterations required by the generalised least squares.
be	The estimated regression coefficients, which in the case of "rint.regbx" are simply two: the constant and the slope (time effect).
ranef	The random intercepts effects.

system.time( for (i in 1:40) a <- rint.reg(y, x, id) )
```

Random values simulation from a von Mises distribution

Random values simulation from a von Mises distribution

Description

It generates random vectors following the von Mises distribution. The data can be spherical or hyper-spherical.

Usage

```
rvonmises(n, m, k, rads = TRUE)
```

Arguments

n	The sample size.
m	The mean angle expressed in radians or degrees.
k	The concentration parameter. If k is zero the sample will be generated from the uniform distribution over $(0, 2\pi)$.
rads	If the mean angle is expressed in radians, this should be TRUE and FALSE otherwise. The simulated data will be expressed in radians or degrees depending on what the mean angle is expressed.

Details

The mean direction is transformed to the Euclidean coordinates (i.e. unit vector) and then the fvmf function is employed. It uses a rejection smapling as suggested by Andrew Wood in 1994. I have mentioned the description of the algorithm as I found it in Dhillon and Sra in 2003. Finally, the data are transformed to radians or degrees.

Value

A vector with the simulated data.

Ranks of the values of a vector

Ranks of the values of a vector

Description

Ranks of the values of a vector.

Usage

```
Rank(x,method = "average",descending = FALSE)
```

Arguments

x	A numerical vector with data.
method	a character string for choosing method. Must be one of "average", "min", "max".
descending	A boolean value (TRUE/FALSE) for sorting the vector in descending order. By default sorts the vector in ascending.

Details

The ranks of the values are returned, the same job as "rank". If you want you can choose descending/ascending order for all methods.

Value

A vector with the ranks of the values.

`Reading the files of a directory`

Reading the files of a directory

Description

Reading the files of a directory.

Usage

```
read.directory(path.directory)
read.examples(path.man)
```

Arguments

`path.directory`	The full path to the directory. For example: \"C:\Users\username\Documents\R\Rfast_1.8.0\R\"
`path.man`	The full path to the directory with the Rd files in it. For example: \"C:\Users\username\Documents\R\Rfast

Details

For function \"read.directory\": Takes as an argument a full path to a directory and returns the names of the files.

For function \"read.examples\": Takes as an argument a full path to the directory of the Rd files. If you don't want the program to read any file add at the top of the file the attribute "%[dont read]".

Value

For function \"read.directory\": The names of the files.

For function \"read.examples\": a list with 2 fields

examples	A character vector with the examples of each Rd file.
files	A character vector with the name of the file that each examples belongs.
long_lines	A character vector with the name of the file that has large examples.

You can choose which files not to read for both R and Rd. You must add in the first line of the file in comment the "attribute" "%[dont read]". Finally, that function wil return in the result a list of which files had this attribute.

# system.time( read.examples(path.man,dont.read=c("somef_1.Rd",...,"somef_n.Rd") ) )
```

`Repeated measures anova`

Repeated measures anova

Description

Repeated measures anova.

Usage

```
rm.anova(y, logged = FALSE)
```

Arguments

y	A matrix with the data, where each column refers to a different measurement. The rows denote the subjects.
logged	Should the p-values be returned (FALSE) or their logarithm (TRUE)?

Details

Found in Davis (2002) is the usual repeated measures ANOVA. In this case, suppose you have taken measurements on one or more variables from the same group of people. See the example below on how to put such data.

Value

A vector with the test statistic (t-test) and its associated p-value.

Author(s)

Michail Tsagris

R implementation and documentation: Michail Tsagris <mtsagris@uoc.gr> and Manos Papadakis <papadakm95@gmail.com>.

```

Replicate columns/rows

Replicate columns/rows

Description

Replicate columns/rows.

Usage

```
rep_col(x,n)
rep_row(x,n)
```

Arguments

x	A vector with data.
n	Number of new columns/rows.

Value

A matrix where each column/row is equal to "x".

Author(s)

Manos Papadakis

R implementation and documentation: Manos Papadakis <papadakm95@gmail.com>.

all.equal(rep_col(x,10),matrix(x,nrow=length(x),ncol=10))
all.equal(rep_row(x,10),matrix(x,ncol=length(x),nrow=10,byrow=TRUE))
```

Represantation of Stack

Represantation of Stack

Description

Represantation of Stack.

Usage

```
Stack(x,type=NULL)
```

Arguments

x	Any type that could be convert to vector or an integer value.
type	A type for the Stack, "integer", "numeric" or any other that accepts one argument.

Details

Stack is an abstract data type - data structure based on the principle of last in first out. To access the 3 fields, use operator "$".

Value

An object of class "Stack". This object holds 3 fields:

pop: remove the first element (from the top). top: access the first element (from the top). push: add an element to the top of the Stack.

Author(s)

R implementation and documentation: Manos Papadakis <papadakm95@gmail.com>.

x<-Stack(10,type=integer)

x$push(5)
x$push(10)
x$top()  == 10
x$pop()
x$top() == 5

y<-rnorm(10)
x<-Stack(x)

x$push(5) # length increased to 11
x$top() # access the last element that pushed, 5
x$pop() # pop the last element that pushed
```

`Round each element of a matrix/vector`

Round each element of a matrix/vector

Description

Round each element of a matrix/vector.

Usage

```
Round(x,digit=0,na.rm = FALSE)
```

Arguments

`x`	A numeric matrix/vector with data or NA. NOT integer values.
`digit`	An integer value for 0...N-1 where N is the number of the digits. By default is 0.
`na.rm`	TRUE or FAlSE for remove NAs if exists.

Details

Round is a very fast C++ implementation. Especially for large data. It handles NA.

Value

A vector/matrix where each element is been rounded in the given digit.

all.equal(a,b) #true
x <-rnorm( 1000)
system.time( a <- Round(x,5) )
system.time( b <- round(x,5) )
all.equal(a,b) # true
```

Row - Wise matrix/vector count the frequency of a value

Row - Wise matrix/vector count the frequency of a value

Description

Row - Wise matrix/vector count the frequency of a value.

Usage

```
count_value(x, value)
colCountValues(x, values, parallel = FALSE)
rowCountValues(x, values, parallel = FALSE)
```

Arguments

x	A vector with the data (numeric or character) or a numeric matrix.
value	The value, numeric or character, to check its frequency in the vector "x".
values	a vector with the values to check its frequency in the matrix "x" by row or column.
parallel	Do you want to do it in parallel in C++? TRUE or FALSE. Works with every other argument.

Details

The functions is written in C++ in order to be as fast as possible. The "x" and "value" must have the same type. The type can be numeric or character.

Value

The frequency of a value/values in a vector in linear time or by row/column in a matrix.

value <- "r"
system.time( count_value(y,value) )
values <- sample(x,100,replace=TRUE)
x <- matrix(x,100,100)
res<-colCountValues(x,values)
res<-rowCountValues(x,values)
x<-value<-values<-y<-NULL
```

Row-wise minimum and maximum

Row-wise minimum and maximum of a matrix.

Description

Row-wise minimum and maximum of a matrix.

Usage

```
rowMins(x, value = FALSE)
rowMaxs(x, value = FALSE)
rowMinsMaxs(x)
```

Arguments

x	A numerical matrix with data.
value	If the value is FALSE it returns the indices of the minimum/maximum, otherwise it returns the minimum and maximum values.

Value

A vector with the relevant values.

system.time( s2 <- apply(x, 1, min) )

system.time( s1 <- rowMaxs(x) )
system.time( s2 <- apply(x, 1, max) )

system.time( s1 <- c(apply(x, 1, min),apply(x, 1, max) ))
system.time( s2 <- rowMinsMaxs(x) )

x<-s1<-s2<-NULL
```

Row-wise true value *Row-wise true value of a matrix*

Description

Row-wise true value of a matrix.

Usage

```
rowTrue(x)
rowFalse(x)
rowTrueFalse(x)
```

Arguments

x	A logical matrix with data.

Value

An integer vector where item "i" is the number of the true/false values of "i" row.

Author(s)

Manos Papadakis

R implementation and documentation: Manos Papadakis <papadakm95@gmail.com>.

s1 <- rowTrue(x)

s1 <- rowFalse(x)

s1 <- rowTrueFalse(x)

x<-s1<-NULL
```

Search for variables with zero range in a matrix

Search for variables with zero range in a matrix

Description

Search for variables with zero range in a matrix.

Usage

```
check_data(x, ina = NULL)
```

Arguments

x	A matrix or a data.frame with the data, where rows denotes the observations and the columns contain the dependent variables.
ina	If your data are grouped, for example there is a factor or numerical variable indicating the groups of the data supply it here, otherwise leave it NULL.

Details

The function identifies the variabels with zero range, instead of a zero variance as this is faster. It will work with matrices and data.frames.

Value

A numerical vector of length zero if no zero ranged variable exists, or of length at least one with the index (or indices) of the variable(s) that need attention or need to be removed.

Author(s)

Michail Tsagris

R implementation and documentation: Michail Tsagris <mtsagris@uoc.gr> and Manos Papadakis <papadakm95@gmail.com>.

x <- matrix( rnorm(100 * 100), ncol = 100 )
res<-check_data(x)

## some variables have a constant value
x[, c(1,10, 50, 70)] <- 1
res<-check_data(x)
id <- rep(1:4, each = 25 )
x[1:25, 2] <- 0
res<-check_data(x)  ## did not use the id variable
res<-check_data(x, id)  ## see now
x <- NULL
```

Significance testing for the coefficients of Quasi binomial or the quasi Poisson regression

Significance testing for the coefficients of Quasi binomial or the quasi Poisson regression

---

Description

Significance testing for the coefficients of Quasi binomial or the quasi Poisson regression.

Usage

```
anova_propreg(mod, poia = NULL)
anova_qpois.reg(mod, poia = NULL)
```

Arguments

`mod`	An object as returned by the "prop.reg" or the "qpois.reg" function.
`poia`	If you want to test the significance of a single coefficient this must be a number. In this case, the "prop.reg" or the "qpois.reg" function contains this information. If you want more coefficients to be testes simultaneously, e.g. for a categorical predictor, then this must contain the positions of the coefficients. If you want to see if all coefficients are zero, like an overall F-test, leave this NULL.

Details

Even though the name of this function starts with anova it is not an ANOVA type significance testing, but a Wald type.

Value

A vector with three elements, the test statistic value, its associated p-value and the relevant degrees of freedom.

```

Simulation of random values from a Bingham distribution

Simulating from a Bingham distribution

Description

Simulation from a Bingham distribution using the code suggested by Kent et al. (2013).

Usage

```
rbing(n, lam)
```

Arguments

n	Sample size.
lam	Eigenvalues of the diagonal symmetric matrix of the Bingham distribution. See details for more information on this.

Details

The user must have calculated the eigenvalues of the diagonal symmetric matrix of the Bingham distribution. The function accepts the q-1 eigenvalues only. This means, that the user must have subtracted the lowest eigenvalue from the rest and give the non zero ones. The function uses rejection sampling.

Value

A matrix with the simulated data.

`Simulation of random values from a Bingham distribution with any symmetric matrix`

Simulation of random values from a Bingham distribution with any symmetric matrix

---

Description

Simulation of random values from a Bingham distribution with any symmetric matrix.

Usage

```
rbingham(n, A)
```

Arguments

`n`	Sample size.
`A`	A symmetric matrix.

Details

The eigenvalues of the q x q symmetric matrix A are calculated and the smallest of them is subtracted from the rest. The q - 1 non zero eiqenvalues are then passed to `rbing`. The generated data are then right multiplied by V^T, where V is the matrix of eigenvectors of the matrix A.

Value

A matrix with the simulated data.

Author(s)

Michail Tsagris

R implementation and documentation: Michail Tsagris <mtsagris@uoc.gr> and Manos Papadakis <papadakm95@gmail.com>

Examples

```
A <- cov( iris[, 1:4] )
x <- rbingham(100, A)
x
```

Simulation of random values from a normal distribution

Simulation of random values from a normal distribution

Description

Simulation of random values from a normal distribution.

Usage

```
Rnorm(n, m = 0, s = 1, seed = NULL)
```

Arguments

n	The sample size.
m	The mean, set to 0 by default.
s	The standard devation, set to 1 by default.
seed	If you want the same to be generated again use a seed for the generator, an integer number.

Details

By using the Ziggurat method of generating standard normal variates, this function is really fast when you want to generate large vectors. For less than 2,000 this might make no difference when compared with R's "rnorm", but for 10,000 this will be 6-7 times faster.

Value

A vector with n values.

Author(s)

Michail Tsagris

R implementation and documentation: Michail Tsagris <mtsagris@uoc.gr>

```

`Simulation of random values from a von Mises-Fisher distribution`

Random values simulation from a von Mises-Fisher distribution

---

Description

It generates random vectors following the von Mises-Fisher distribution. The data can be spherical or hyper-spherical.

Usage

```
rvmf(n, mu, k)
```

Arguments

`n`	The sample size.
`mu`	The mean direction, a unit vector.
`k`	The concentration parameter. If k = 0, random values from the spherical uniform will be drwan. Values from a multivariate normal distribution with zero mean vector and the identity matrix as the covariance matrix. Then each vector becomes a unit vector.

Details

It uses a rejection smapling as suggested by Andrew Wood (1994).

Value

A matrix with the simulated data.

Skeleton of the PC algorithm

The skeleton of a Bayesian network produced by the PC algorithm

---

Description

The skeleton of a Bayesian network produced by the PC algorithm.

Usage

```
pc.skel(dataset, method = "pearson", alpha = 0.01, R = 1, stat = NULL, ini.pvalue = NULL)
```

Arguments

dataset	A numerical matrix with the variables. If you have a data.frame (i.e. categorical data) turn them into a matrix using data.frame.to_matrix. Note, that for the categorical case data, the numbers must start from 0. No missing data are allowed.
method	If you have continuous data, you can choose either "pearson" or "spearman". If you have categorical data though, this must be "cat". In this case, make sure the minimum value of each variable is zero. The g2Test and the relevant functions work that way.
alpha	The significance level (suitable values in (0, 1)) for assessing the p-values. Default (preferred) value is 0.01.
R	The number of permutations to be conducted. The p-values are assessed via permutations. Use the default value if you want no permutation based assessment.
stat	If the initial test statistics (univariate associations) are available, pass them through this parameter.
ini.pvalue	if the initial p-values of the univariate associations are available, pass them through this parameter.

Details

The PC algorithm as proposed by Spirtes et al. (2000) is implemented. The variables must be either continuous or categorical, only. The skeleton of the PC algorithm is order independent, since we are using the third heuristic (Spirte et al., 2000, pg. 90). At every stage of the algorithm use the pairs which are least statistically associated. The conditioning set consists of variables which are most statistically associated with each other of the pair of variables.

For example, for the pair (X, Y) there can be two conditioning sets for example (Z1, Z2) and (W1, W2). All p-values and test statistics and degrees of freedom have been computed at the first step of the algorithm. Take the p-values between (Z1, Z2) and (X, Y) and between (Z1, Z2) and (X, Y). The conditioning set with the minimum p-value is used first. If the minimum p-values are the same, use the second lowest p-value. If the unlikely, but not impossible, event of all p-values being the same, the test statistic divided by the degrees of freedom is used as a means of choosing which conditioning set is to be used first.

If two or more p-values are below the machine epsilon (.Machine$double.eps which is equal to 2.220446e-16), all of them are set to 0. To make the comparison or the ordering feasible we use the logarithm of p-value. Hence, the logarithm of the p-values is always calculated and used.

In the case of the G^2 test of independence (for categorical data) with no permutations, we have incorporated a rule of thumb. If the number of samples is at least 5 times the number of the parameters to be estimated, the test is performed, otherwise, independence is not rejected according to Tsamardinos et al. (2006). We have modified it so that it calculates the p-value using permutations.

Value

A list including:

`stat`	The test statistics of the univariate associations.
`ini.pvalue`	The initial p-values univariate associations.
`pvalue`	The logarithm of the p-values of the univariate associations.
`runtime`	The amount of time it took to run the algorithm.
`kappa`	The maximum value of k, the maximum cardinality of the conditioning set at which the algorithm stopped.
`n.tests`	The number of tests conducted during each k.
`G`	The adjancency matrix. A value of 1 in G[i, j] appears in G[j, i] also, indicating that i and j have an edge between them.
`sepset`	A list with the separating sets for every value of k.

Author(s)

Marios Dimitriadis.

```

Skewness and kurtosis coefficients

Skewness and kurtosis coefficients

Description

Skewness and kurtosis coefficients.

Usage

```
skew(x, pvalue = FALSE)

kurt(x, pvalue = FALSE)
```

Arguments

x	A numerical vector with data.
pvalue	If you want a hypothesis test that the skewness or kurtosis are significant set this to TRUE. This checks whether the skewness is significantly different from 0 and whether the kurtosis is significantly different from 3.

Details

The sample skewness and kurtosis coefficient are calculated. For the kurtosis we do not subtract 3.

Value

If "pvalue" is FALSE (default value) the skewness or kurtosis coefficients are returned. Otherwise, the p-value of the significance of the coefficient is returned.

Some summary statistics of a vector for each level of a grouping variable

Some summary statistics of a vector for each level of a grouping variable.

Description

Some summary statistics of a vector for each level of a grouping variable.

Usage

```
group(x,ina,method="sum",ina.min=NULL,ina.max = NULL,
ina.length.unique=NULL,mad.method="median")
group.sum(x, ina,ina.max = NULL,ina.min = NULL)
group.mean(x, ina,ina.max = max(ina))
```

Arguments

`x`	A numerical vector with data.
`ina`	A numerical vector with numbers. Note that zero and negative values are not allowed as this can cause R to run forever or crash.
`ina.length.unique`	Length of the unique numerical values of ina argument.
`method`	A character vector with values "sum", "var", "all", "any", "mad", "mean", "med", "min", "max", "min.max".
`ina.max`	Maximum number for vector ina.
`ina.min`	Minimum number for vector ina.
`mad.method`	A character vector with values "median", for median absolute deviation or "mean", for mean absolute deviation. This works only with method="mad".

Details

This command works only for vectors. Median absolute deviation, mean, median, minimum, maximum are some of the options offered.

Value

A vector with the variance, or standard deviation, or mean, or minimum, or maximum, or median, or minimum-maximum of x for each distinct value of ina.

Author(s)

Manos Papadakis and Michail Tsagris

R implementation and documentation: Manos Papadakis <papadakm95@gmail.com> and Michail Tsagris <mtsagris@uoc.gr>.

res<-group(x, ina,method="var")
```

Sort - Integer Sort - Sort a vector coresponding to another

Sort - Integer Sort - Sort a vector coresponding to another

Description

Fast sorting a vector.

Usage

```
Sort(x,descending=FALSE,partial=NULL,stable=FALSE,na.last=NULL)
Sort.int(x)
sort_cor_vectors(x, base, stable = FALSE, descending = FALSE)
```

Arguments

x	A numerical/integer/character vector with data.
base	A numerical/character vector to help sorting the x.
descending	A boolean value (TRUE/FALSE) for sorting the vector in descending order. By default sorts the vector in ascending.
partial	This argument has two usages. The first is an index number for sorting partial the vector. The second is a vector with 2 values, start and end c(start,end). Gives you a vector where the elements between start and end will be sorted only. Not character vector.
stable	A boolean value (TRUE/FALSE) for choosing a stable sort algorithm. Stable means that discriminates on the same elements. Not character vector.
na.last	Accept 4 values. TRUE, FALSE, NA, NULL. TRUE/FALSE: for put NAs last or first. NA: for remove NAs completely from vector. NULL: by default. Leave it like that if there is no NA values.

Details

This function uses the sorting algorithm from C++. The implementation is very fast and highly optimised. Especially for large data.

Value

Sort and Sort.int: The sorted vector.

sort_cor_vectors: The first argument but sorted acording to the second.

Author(s)

Manos Papadakis

R implementation and documentation: Manos Papadakis <papadakm95@gmail.com>.

x<-rpois(100,100)
all.equal(Sort.int(x),sort.int(x))

x<-y<-y<-s1<-s2<-NULL
```

`Sort and unique numbers`

Sort and unique

Description

Sort and unique numbers.

Usage

```
sort_unique(x)
sort_unique.length(x)
```

Arguments

x	A numeric vector.

Details

The "sort_unique" function implements R's "unique" function using C++'s function but also sort the result. The "sort_unique.length" returns the length of the unique numbers only for **itegers**.

Value

Returns the discrete values but sorted or their length (depending on the function you do).

Author(s)

Manos Papadakis

R implementation and documentation: Manos Papadakis <papadakm95@gmail.com>

sort_unique.length(x)
length(sort_unique(x))

x<-a<-b<-NULL
```

Sorting of the columns-rows of a matrix

Sorting of the columns-rows of a matrix

Description

Fast sorting of the columns-rows of a matrix.

Usage

```
colSort(x, descending = FALSE, stable = FALSE,parallel=FALSE)
rowSort(x, descending = FALSE, stable = FALSE,parallel=FALSE)
sort_mat(x,by.row=FALSE,descending=FALSE,stable=FALSE,parallel=FALSE)
```

Arguments

x	A numerical matrix with data.
descending	If you want the sorting in descending order, set this to TRUE.
stable	If you the stable version, so that the results are the same as R's (in the case of ties) set this to TRUE. If this is TRUE, the algorithm is a bit slower.
parallel	Do you want to do it in parallel in C++? TRUE or FALSE. Works with every other argument.
by.row	TRUE or FALSE for applying sort in rows or column.

Value

The matrix with its columns-rows (or rows) independently sorted.

Author(s)

Manos Papadakis

R implementation and documentation: Manos Papadakis <papadakm95@gmail.com>.

system.time( s2 <- apply(x, 2, sort)  )
all.equal(as.vector(s1), as.vector(s2))

x<-NULL
```

Source many R files *Source many R files*

Description

Source many R/Rd files.

Usage

```
sourceR(path,local=FALSE,encode = "UTF-8",print.errors=FALSE)
sourceRd(path,print.errors=FALSE)
```

Arguments

path	An full path to the directory where R file are.
local	TRUE, FALSE or an environment, determining where the parsed expressions are evaluated. FALSE (the default) corresponds to the user's workspace (the global environment) and TRUE to the environment from which source is called.
encode	Character vector. The encoding(s) to be assumed when file is a character string: see file. A possible value is "unknown" when the encoding is guessed: see the "Encodings" section.
print.errors	A boolean value (TRUE/FALSE) for printing the errors, if exists, for every file.

Details

Reads many R files and source them.

Value

Returns the files that had produced errors during source.

Author(s)

R implementation and documentation: Manos Papadakis <papadakm95@gmail.com>.

# system.time( a<-sourceRd(path) )
```

`Spatial median for Euclidean data`
Spatial median for Euclidean data

Description

Spatial median for Euclidean data.

Usage

```
spat.med(x, tol = 1e-09)
```

Arguments

`x`	A matrix with Euclidean data, continuous variables.
`tol`	A tolerance level to terminate the process. This is set to 1e-09 by default.

Details

The spatial median, using a fixed point iterative algorithm, for Euclidean data is calculated. It is a robust location estimate.

Value

A vector with the spatial median.

Author(s)

Manos Papadakis and Michail Tsagris

R implementation and documentation: Michail Tsagris <mtsagris@uoc.gr> and Manos Papadakis <papadakm95@gmail.com>

```

`Spatial median regression`

Spatial median regression

Description

Spatial median regression with Euclidean data.

Usage

```
spatmed.reg(y, x, tol = 1e-07)
```

Arguments

`y`	A matrix with the response variable.
`x`	The predictor variable(s), they have to be continuous.
`tol`	The threshold upon which to stop the iterations of the Newton-Rapshon algorithm.

Details

The objective function is the minimization of the sum of the absolute residuals. It is the multivariate generalisation of the median regression.

Value

A list including:

`iters`	The number of iterations that were required.
`be`	The beta coefficients.

`Spatial sign covariance matrix`

Spatial sign covariance matrix

Description

Spatial sign covariance matrix.

Usage

```
sscov(x, me = NULL, tol = 1e-09)
```

Arguments

`x`	A matrix with continuous data.
`me`	If you have already computed the spatial median plug it in here.
`tol`	A tolerance level to terminate the process of finding the spatial median. This is set to 1e-09 by default.

Details

The spatial median is at first computed (if not supplied) and then the covariance matrix.

Value

The spatial sign covariance matrix.

Author(s)

Michail Tsagris

R implementation and documentation: Michail Tsagris <mtsagris@uoc.gr>.

Spherical and hyperspherical median

Fast calculation of the spherical and hyperspherical median

Description

It calculates, very fast, the (hyper-)spherical median of a sample.

Usage

```
mediandir(x)
```

Arguments

x	The data, a numeric matrix with unit vectors.

Details

The "mediandir" employes a fixed poit iterative algorithm stemming from the first derivative (Cabrera and Watson, 1990) to find the median direction as described in Fisher (1985) and Fisher, Lewis and Embleton (1987).

Value

The median direction.

Author(s)

Michail Tsagris

R implementation and documentation: Michail Tsagris <mtsagris@uoc.gr>

m <- m / sqrt( sum(m^2) )
x <- rvmf(100, m, 10)
res<-mediandir(x)
x <- NULL
```

`Standardisation` *Standardisation*

Description

Standardisation.

Usage

```
standardise(x, center = TRUE, scale = TRUE)
```

Arguments

`x`	A matrix with data. It has to be matrix, if it is data.frame for example the function does not turn it into a matrix.
`center`	Should the data be centred as well? TRUE or FALSE.
`scale`	Should the columns have unit variance, yes (TRUE) or no (FALSE)?

Details

Similar to R's built in functions "scale" there is the option for centering or scaling only or both (default).

Value

A matrix with the standardised data.

Author(s)

Michail Tsagris

R implementation and documentation: Michail Tsagris <mtsagris@uoc.gr> and Manos Papadakis <papadakm95@gmail.com>.

See Also

colVars, colmeans, colMads

Examples

```
x <- matrnorm( 100, 100 )
a1 <- scale(x)[1:100, ]
a2 <- standardise(x)
all.equal(as.vector(a1), as.vector(a2))
x <- NULL
```

Sub-matrix *Sub-matrix*

Description

Sub-matrix.

Usage

```
submatrix(x,rowStart=1,rowEnd=1,colStart=1,colEnd=1)
```

Arguments

x	A Matrix, List, Dataframe or Vector.
rowStart	Start of the row.
rowEnd	End of the row.
colStart	Start of the col.
colEnd	End of the col.

Value

sub matrix like R's, x[startrow:endrow,startcol:endcol]. Fast especially for big sub matrices.

Author(s)

Manos Papadakis

R implementation and documentation: Manos Papadakis <papadakm95@gmail.com>.

Examples

```
x <- matrix( rnorm(100 * 100), ncol = 100 )
res<-submatrix(x,1,50,1,25) # x[1:50,1:25]

x<-NULL
```

Sum of all pairwise distances in a distance matrix

Sum of all pairwise distances in a distance matrix

Description

Sum of all pairwise distances in a distance matrix.

Usage

```
total.dist(x, method = "euclidean", square = FALSE, p = 0)
total.dista(x, y, square = FALSE)
```

Arguments

x	A matrix with numbers.
y	A second matrix with data. The number of comlumns of this matrix must be the same with the matrix x. The number of rows can be different.
method	This is either "euclidean", "manhattan", "canberra1", "canberra2", "minimum", "maximum", "minkowski","bhattacharyya", "hellinger", "total_variation" or "kullback_leibler/jensen_shannon". The last two options are basically the same.
square	If you choose "euclidean" or "hellinger" as the method, then you can have the option to return the squared Euclidean distances by setting this argument to TRUE.
p	This is for the the Minkowski, the power of the metric.

Details

In order to do the total.dist one would have to calcualte the distance matrix and sum it. We do this internally in C++ without creating the matrix. For the total.dista it is the same thing.

Value

A numerical value, the sum of the distances.

Author(s)

Manos Papadakis

R implementation and documentation: Manos Papadakis <papadakm95@gmail.com>.

See Also

Dist, dista

Examples

```
x <- matrix( rnorm(50 * 10), ncol = 10 )
res<-total.dist(x)
y <- matrix( rnorm(40 * 10), ncol = 10)
res<-total.dista(x, y)
res<-total.dista(y, x)

x<-y<-NULL
```

Table Creation - Frequency of each value

Table Creation - Frequency of each value

Description

Table Creation - Frequency of each value.

Usage

```
Table(x,y=NULL,names = TRUE,useNA = FALSE,rm.zeros = FALSE)
Table.sign(x,names = TRUE,useNA = FALSE)
```

Arguments

x	A vector with numeric/character data.
names	A logical value (TRUE/FALSE) for add names.
y	A vector with numeric/character data. Doesn't work with "useNA".
rm.zeros	A logical value for removing zero columns/rows. Only for integer vectors for now.

`useNA` Table: Integer/logical value:

FALSE: not NA values in vector. TRUE: count NAs and add the value in the last position of the returned vector. any other integer except 0,1: for just removing NAs.

Table.sign: Logical value, TRUE, for count NAs. Otherwise FALSE.

Doesn't work character data.

Details

Like R's "table":

for giving one argument,"x": If "names" is FALSE then, if "useNA" is TRUE then the NAs will be count, if is FALSE it means there are no NAs and for any other integer value the NAs will be ignored.

for giving two arguments,"x","y": If "names" is FALSE then, creates the contigency table, otherwise sets the col-row names with discrete values. If "rm.zeros" is FALSE then it won't remove the zero columns/rows from the result but it will work only for positive integers for now. For this if "names" is TRUE then the col-row names will be the seq(min(),max()) for "x","y". In future updates it will be changed.

for both algorithms: You can't use "useNA" with "names" for now. It is much faster to get the result without names (names = FALSE) but all the algorithms are more efficient than R's.

Like R's "table(sign())" but more efficient. Count the frequencies of positives, negatives, zeros and NAs values. If argument "names" is FALSE then the returned vector doesn't have names. Otherwise "-1,0,+1,NA". If "useNA" is TRUE then the NAs will be count, otherwise not. You can use "useNA" with "names".

Value

Table:

for giving one argument,"x": if "names" is TRUE then return a vector with names the discrete values of "x" and values there frequencies, otherwise only the frequencies

for giving two arguments,"x","y": if "names" is TRUE then return a contigency matrix with row-names the discrete values of "x", colnames the dicrete values of "y" and values the freuquencies of the pairs, otherwise only the freuquencies of the pairs.

Table.sign: A vector with 4 values/frequencies: index 1: negatives index 2: zeros index 3: postives if "names" is TRUE then the returned vector have names "-1,0,+1". if "useNA" is TRUE then 4th value has the frequencies of NAs and the returned vector will have one more name, "-1,0,+1,NA", if "names" is also TRUE.

y1<-Table(x,names=FALSE)
all.equal(y1,y2) # the name attribute of y1 is null

y1<-Table.sign(x)
y2<-table(sign(x))
all.equal(y1,y2)

x<-y1<-y2<-NULL
```

Tests for the dispersion parameter in Poisson distribution

Tests for the dispersion parameter in Poisson distribution

Description

Tests for the dispersion parameter in Poisson distribution.

Usage

```
poisdisp.test(y, alternative = "either", logged = FALSE)
pois.test(y, logged = FALSE)
```

Arguments

y	A numerical vector with count data, 0, 1,...
alternative	Do you want to test specifically for either over or underspirsion ("either"), overdispersion ("over") or undersispersion ("under")?
logged	Set to TRUE if you want the logarithm of the p-value.

Value

A vector with two elements, the test statistic and the (logged) p-value.

res<-pois.test(y)
```

`Topological sort of a DAG`

Topological sort of a DAG

Description

Topological sort of a DAG.

Usage

```
topological_sort(dag)
```

Arguments

`dag`	A square matrix representing a directed graph which contains 0s and 1s. If G[i, j] = 1 it means there is an arrow from node i to node j. When there is no edge between nodes i and j if G[i, j] = 0.

Details

The function is an R translation from an old matlab code.

Value

A vector with numbers indicating the sorting. If the dag is not a Directed acyclic Graph, NA will be returned.

```

Uniformity test for circular data

Uniformity tests for circular data

Description

Hypothesis tests of uniformity for circular data.

Usage

```
kuiper(u)

watson(u)
```

Arguments

u	A numeric vector containing the circular data which are expressed in radians.

Details

These tests are used to test the hypothesis that the data come from a circular uniform distribution.

Value

A vector with two elements, the value of the test statistic and its associated p-value.

res<-kuiper(x)
res<-watson(x)
```

Variance of a vector *Variance (and standard deviation) of a vector*

Description

Variance (and standard deviation) of a vector.

Usage

```
Var(x, std = FALSE,na.rm = FALSE)
```

Arguments

x	A vector with data.
std	If you want the standard deviation set this to TRUE, otherwise leave it FALSE.
na.rm	TRUE or FAlSE for remove NAs if exists.

Details

This is a faster calculation of the usual variance of a matrix.

Value

The variance of the vector.

Description

Vector allocation in a symmetric matrix.

Usage

```
squareform(x)
```

Arguments

`x`	An numverical vector whose size must be the one that matches the dimensions of the final matrix. See examples.

Details

The functions is written in C++ in order to be as fast as possible.

Value

A symmetric matrix. The vector is allocated in the upper and in the lower part of the matrix. The diagonal is filled with zeros.

Author(s)

R implementation and documentation: Manos Papadakis <papadakm95@gmail.com>.

See Also

colShuffle, colVars, colmeans

Examples

```
x <- rnorm(1)
res<-squareform(x)  ## OK
x <- rnorm(3)
res<-squareform(x)  ## OK
x <- rnorm(4)
res<-squareform(x)  ## not OK
```

Weibull regression model

Weibull regression model

Description

Weibull regression model.

Usage

```
weib.reg(y, x, tol = 1e-07, maxiters = 100)
```

Arguments

y	The dependent variable; a numerical vector with strictly positive data, i.e. greater than zero.
x	A matrix with the data, where the rows denote the samples (and the two groups) and the columns are the variables. This can be a matrix or a data.frame (with factors).
tol	The tolerance value to terminate the Newton-Raphson algorithm.
maxiters	The max number of iterations that can take place in each regression.

Details

The function is written in C++ and this is why it is very fast. No standard errors are returned as they are not corectly estimated. We focused on speed.

Value

When full is FALSE a list including:

iters	The iterations required by the Newton-Raphson.
loglik	The log-likelihood of the model.
shape	The shape parameter of the Weibull regression.
be	The regression coefficients.

Examples

```
x <- matrix(rnorm(100 * 2), ncol = 2)
y <- rexp(100, 1)
res<-weib.reg(y, x)
```

`Yule's Y (coefficient of colligation)`

Yule's Y (coefficient of colligation)

Description

Yule's Y (coefficient of colligation).

Usage

```
yule(x)
```

Arguments

x	A 2 x 2 matrix or a vector with 4 elements. In the case of the vector make sure it corresponds to the correct table.

Details

Yule's coefficient of colligation is calculated.

Value

Yule's Y is returned.

Author(s)

Median of a vector, 186
* **one sample**
Empirical and exponential empirical likelihood tests for one sample, 82
Many one sample tests, 156
* **operations**
Operations between two matrices or matrix and vector, 224
* **outliers**
High dimensional MCD based detection of outliers, 111
* **partial correlation**
BIC (using partial correlation) forward regression, 19
Correlation based forward regression, 62
* **percentages**
Hypothesis test for two means of

percentages, 114
Many hypothesis tests for two means of percentages, 147
* **poisson regression**
Logistic and Poisson regression models, 130
* **positive definite**
Inverse of a symmetric positive definite matrix, 120
* **positive multivariate data**
MLE of the inverted Dirichlet distribution, 201
* **positive numbers**
Apply method to Positive and Negative number, 15
* **projected normal distribution**
MLE of (hyper-)spherical distributions, 191
* **projected normal**
Circular or angular regression, 32
Many simple circular or angular regressions, 164
* **proportion test**
Many one sample tests, 156
* **proportional odds**
MLE of the ordinal model without covariates, 205
* **proportions**
Forward selection with generalised linear regression models, 101
MLE of distributions defined in the (0, 1) interval, 198
* **random values simulation**
Angular central Gaussian random values simulation, 13
Multivariate Laplace random values simulation, 213
Multivariate normal and t random values simulation, 214
* **regression**
Many regression based tests for single sample repeated measures, 159
Multinomial regression, 211
Repeated measures anova, 242
* **robust statistics**
Pooled covariance matrix, 232
Spatial median for Euclidean data, 265
Spatial sign covariance matrix, 267
* **row means**
Column and row-wise means of a matrix, 37
* **row-wise maximum**
Row-wise minimum and maximum, 247
* **row-wise variances**
Column and row-wise variances and standard deviations, 48
* **score based tests**
Many score based regressions, 161
* **shortest paths**
Floyd-Warshall algorithm, 99
* **single categorical predictor**
Logistic or Poisson regression with a single categorical predictor, 131
* **sorting**
Median of a vector, 186
* **spatial median**
Spatial median for Euclidean data, 265
* **spherical data**
MLE of (hyper-)spherical distributions, 191
* **summary statistics**
Many regression based tests for single sample repeated measures, 159
Repeated measures anova, 242
* **symmetric matrix**
Inverse of a symmetric positive definite matrix, 120
Vector allocation in a symmetric matrix, 279
* **t distribution**
MLE of continuous univariate distributions defined on the real line, 195
* **t-tests**
Many 2 sample tests, 137
Many hypothesis tests for two means of percentages, 147
Matrix with all pairs of t-tests, 182
* **t-test**
Hypothesis test for two means of

percentages, 114
Many one sample tests, 156
∗ **total sum**
Energy distance between matrices, 85
Sum of all pairwise distances in a distance matrix, 271
∗ **trigamma function**
Natural logarithm of the gamma function and its derivatives, 219
∗ **two samples**
Empirical and exponential empirical likelihood tests for two samples, 83
∗ **uniformity tests**
Column-wise uniformity Watson test for circular data, 58
∗ **uniformity test**
Uniformity test for circular data, 277
∗ **unique numbers**
Sort and unique numbers, 262
∗ **univariate approach**
Many regression based tests for single sample repeated measures, 159
Repeated measures anova, 242
∗ **variable selection**
Forward selection with generalised linear regression models, 101
∗ **variance test**
Many one sample tests, 156
∗ **variances of many samples**
Column and row-wise variances and standard deviations, 48
∗ **von Mises distribution**
MLE of some circular distributions, 200
∗ **von Mises-Fisher distribution**
Hypothesis test for von Mises-Fisher distribution over Kent distribution, 115
MLE of (hyper-)spherical distributions, 191
Random values simulation from a von Mises distribution, 239
Simulation of random values from a von Mises-Fisher distribution, 255
∗ **wrapped Cauchy distribution**
MLE of some circular distributions, 200
∗ **zero inflated Poisson**
MLE of count data (univariate discrete distributions), 196
∗ **zero truncated Poisson**
MLE of count data (univariate discrete distributions), 196

Round, *16*, *261*
Round *(*Round each element of a matrix/vector*)*, 245
Round each element of a matrix/vector, 245
Row - Wise matrix/vector count the frequency of a value, 246

Row-wise minimum and maximum, 247
Row-wise true value, 248
rowAll (Column and row-wise Any/All), 36
rowAny (Column and row-wise Any/All), 36
rowCountValues (Row - Wise matrix/vector count the frequency of a value), 246
rowcvs (Column and row wise coefficients of variation), 35
rowFalse, *25*, *57*, *108*, *244*
rowFalse (Row-wise true value), 248
rowhameans (Column and row-wise means of a matrix), 37
rowMads, *225*
rowMads (Column and rows-wise mean absolute deviations), 49
rowMaxs, *43*, *55*, *188, 189*
rowMaxs (Row-wise minimum and maximum), 247
rowmeans (Column and row-wise means of a matrix), 37
rowMedians, *49*, *76*, *133*, *249*
rowMedians (Column and row-wise medians), 38
rowMins, *25*, *43*, *55*, *57*, *76*, *108*, *133*, *188, 189*, *244*, *249*
rowMins (Row-wise minimum and maximum), 247
rowMinsMaxs (Row-wise minimum and maximum), 247
rownth, *16*, *261*
rownth (Column and row-wise nth smallest value of a matrix/vector), 39
rowOrder (Column and row-wise Order - Sort Indices), 41
rowprods (Column and row-wise products), 42
rowrange, *76*, *133*, *248, 249*
rowrange (Column and row-wise range of values of a matrix), 43
rowRanks (Column and row-wise ranks), 44
rows (Get specific columns/rows fo a matrix), 107
rowShuffle (Column and row-wise Shuffle), 45
rowSort, *25*, *43*, *55*, *57*, *76*, *100*, *108*, *187–189*, *244*, *248*, *263*
rowSort (Sorting of the columns-rows of a matrix), 263
rowsums, *38*
rowsums (Column and row-wise sums of a matrix), 46
rowTabulate (Column and row-wise tabulate), 47
rowTrue, *25*, *57*, *108*, *244*
rowTrue (Row-wise true value), 248
rowTrueFalse (Row-wise true value), 248
rowVars, *76*, *133*, *249*
rowVars (Column and row-wise variances and standard deviations), 48
rvmf, *107*, *192*, *201*, *240*, *252*, *254*
rvmf (Simulation of random values from a von Mises-Fisher distribution), 255
rvonmises, *58*, *107*, *201*, *254*, *256*, *278*
rvonmises (Random values simulation from a von Mises distribution), 239

score.betaregs (Many score based regressions), 161
score.expregs (Many score based regressions), 161
score.gammaregs (Many score based regressions), 161
score.geomregs, *166*, *169*
score.geomregs (Many score based regressions), 161

score.invgaussregs (Many score based regressions), 161
score.multinomregs, *211*
score.multinomregs (Many score based regressions), 161
score.negbinregs (Many score based regressions), 161
score.weibregs (Many score based regressions), 161
score.ztpregs (Many score based regressions), 161
Search for variables with zero range in a matrix, 249

sftest (Many Shapiro-Francia normality tests), 163
sftests, *52*, *107*
sftests (Many Shapiro-Francia normality tests), 163
Significance testing for the coefficients of Quasi binomial or the quasi Poisson regression, 250
Simulation of random values from a Bingham distribution, 252
Simulation of random values from a Bingham distribution with any symmetric matrix, 253
Simulation of random values from a normal distribution, 254
Simulation of random values from a von Mises-Fisher distribution, 255
Skeleton of the PC algorithm, 256
skew, *52*, *116*
skew (Skewness and kurtosis coefficients), 258
skew.test2, *52*, *212*, *259*
skew.test2 (Hypothesis testing between two skewness or kurtosis coefficients), 116
Skewness and kurtosis coefficients, 258
Some summary statistics of a vector for each level of a grouping variable, 259
Sort, *50*, *187*
Sort (Sort - Integer Sort - Sort a vector coresponding to another), 260
Sort - Integer Sort - Sort a vector coresponding to another, 260
Sort and unique numbers, 262
sort_cor_vectors, *263*, *264*
sort_cor_vectors (Sort - Integer Sort - Sort a vector coresponding to another), 260
sort_mat (Sorting of the columns-rows of a matrix), 263
sort_unique, *16*, *261*, *264*
sort_unique (Sort and unique numbers), 262
Sorting of the columns-rows of a matrix, 263
Source many R files, 264
sourceR, *28*, *242*
sourceR (Source many R files), 264
sourceRd, *28*, *242*
sourceRd (Source many R files), 264
spat.med, *232*, *267*, *268*
spat.med (Spatial median for Euclidean data), 265
Spatial median for Euclidean data, 265
Spatial median regression, 266
Spatial sign covariance matrix, 267
spatmed.reg, *232*, *268*
spatmed.reg (Spatial median regression), 266
spdinv (Inverse of a symmetric positive definite matrix), 120
Spherical and hyperspherical median, 268
spml.mle, *33*, *127*, *165*
spml.mle (MLE of some circular distributions), 200
spml.reg, *34*
spml.reg (Circular or angular regression), 32
spml.regs (Many simple circular or angular regressions), 164
squareform (Vector allocation in a symmetric matrix), 279
sscov, *267*
sscov (Spatial sign covariance matrix), 267
Standardisation, 269
standardise (Standardisation), 269
Sub-matrix, 270
submatrix (Sub-matrix), 270
Sum of all pairwise distances in a distance matrix, 271

Table, *68*, *231*
Table (Table Creation - Frequency of each value), 272
Table Creation - Frequency of each value, 272
Tcrossprod, *66*, *81*
Tcrossprod (Matrix multiplication), 181
Tests for the dispersion parameter in Poisson distribution, 274
tmle (MLE of continuous univariate distributions defined on the

real line), 195
tobit.mle (MLE of the tobit model), 206
Topological sort of a DAG, 275
topological_sort (Topological sort of a DAG), 275
total.dist, *77*, *86*
total.dist (Sum of all pairwise distances in a distance matrix), 271
total.dista, *77*, *86*
total.dista (Sum of all pairwise distances in a distance matrix), 271
transpose, *181*
transpose (Transpose of a matrix), 276
Transpose of a matrix, 276
Trigamma (Natural logarithm of the gamma function and its derivatives), 219
ttest, *84*, *136*, *138*, *155*, *164*, *183*, *224*
ttest (Many one sample tests), 156
ttest1, *83*
ttest1 (One sample t-test for a vector), 223
ttest2, *24*, *90*, *114*, *142*, *148*
ttest2 (Multi-sample tests for vectors), 209
ttests, *12*, *84*, *136*, *137*, *141*, *144*, *151*, *155*, *157*, *164*, *173*, *183*, *210*, *224*
ttests (Many 2 sample tests), 137
ttests.pairs (Matrix with all pairs of t-tests), 182
twoway.anova (Multi-sample tests for vectors), 209
twoway.anovas (Many two-way ANOVAs), 172

ufactor (Fast and general - untyped represantation of a factor variable), 93
Uniformity test for circular data, 277
univglms, *15*, *18*, *20*, *21*, *63*, *65*, *87*, *103*, *131*, *143*, *146*, *152*, *162*, *167*, *168*, *176*, *177*, *179*, *184*, *235*, *237*, *251*, *271*, *281*
univglms (Many univariate generalised linear models), 173
univglms2 (Many univariate generalised linear models), 173
upper_tri (Lower and Upper triangular of a matrix), 133

Var (Variance of a vector), 278
var2test (Multi-sample tests for vectors), 209
var2tests (Many 2 sample tests), 137
varcomps.mle, *88*, *149*, *160*, *243*
varcomps.mle (Moment and maximum likelihood estimation of variance components), 207
varcomps.mom, *158*, *239*
varcomps.mom (Moment and maximum likelihood estimation of variance components), 207
Variance of a vector, 278
vartest (Many one sample tests), 156
vartests (Many multi-sample tests), 150
vecdist, *228*
vecdist (Distance matrix), 78
Vector allocation in a symmetric matrix, 279
vm.mle, *56*, *192*, *196*, *240*
vm.mle (MLE of some circular distributions), 200
vmf.mle, *58*, *115*, *127*, *201*, *256*, *269*, *278*
vmf.mle (MLE of (hyper-)spherical distributions), 191

watson, *58*
watson (Uniformity test for circular data), 277
weib.reg (Weibull regression model), 280
Weibull regression model, 280
weibull.mle (MLE of continuous univariate distributions defined on the positive line), 193
which.is (Index of the columns of a data.frame which are a specific type), 117
wigner.mle (MLE of continuous univariate distributions defined on the real line), 195
wrapcauchy.mle (MLE of some circular distributions), 200

XopY.sum (Operations between two matrices or matrix and vector), 224

yule, *59*
yule *(*Yule's Y (coefficient of colligation)*)*, 281
Yule's Y (coefficient of colligation), 281

zip.mle, *191*, *194*, *196*
zip.mle *(*MLE of count data (univariate discrete distributions)*)*, 196
ztp.mle, *191*
ztp.mle *(*MLE of count data (univariate discrete distributions)*)*, 196
