

Creating a simple emulator case study from scratch: a cookbook

Robin K. S. Hankin
Auckland University of Technology

Abstract

This document constructs a minimal working example of a simple application of the **emulator** package, step by step. Datasets and functions have a `.vig` suffix, representing “vignette”.

Keywords: emulator, BACCO, R.

1. Introduction

Package **emulator** of bundle **BACCO** performs Bayesian emulation of computer models. This document constructs a minimal working example of a simple problem, step by step. Datasets and functions have a `.vig` suffix, representing “vignette”.

This document is not a substitute for [Kennedy and O’Hagan \(2001a\)](#) or [Kennedy and O’Hagan \(2001b\)](#) or [Hankin \(2005\)](#) or the online help files in **BACCO**. It is not intended to stand alone: for example, the notation used here is that of [Kennedy and O’Hagan \(2001a,b\)](#), and the user is expected to consult the online help in the **BACCO** package when appropriate.

This document is primarily didactic, although it is informal.

Nevertheless, many of the points raised here are duplicated in the **BACCO** helpfiles.

The author would be delighted to know of any improvements or suggestions. Email me at hankin.rob@gmail.com.

2. List of objects that the user needs to supply

The user needs to supply three objects:

- A design matrix, here `val.vig` (rows of this show where the code has been evaluated)
- Basis functions. Here `basis.vig()`. This shows the basis functions used for fitting the prior
- Data, here `z.vig`. This shows the data obtained from evaluating the various levels of code at the points given by the design matrix and the subsets object.

Each of these is discussed in a separate subsection below.

But the first thing we need to do is install the library:

2.1. Design matrix: USER TO SUPPLY

In these sections I show the objects that the user needs to supply, under a heading like the one above. In the case of the `emulator` we need a design matrix and a vector of outputs.

The first thing needed is the design matrix `val.vig`, ie the points in parameter space at which the lowest-level code is executed. The example here has just two parameters, `a` and `b`:

```
> head(val.vig)

      [,1]      [,2]
[1,] 0.8166667 0.1833333
[2,] 0.2500000 0.1166667
[3,] 0.4833333 0.7166667
[4,] 0.8833333 0.2833333
[5,] 0.3833333 0.6833333
[6,] 0.3500000 0.2500000
```

```
> nrow(val.vig)
```

```
[1] 30
```

Notes

- Each row is a point in parameter space, here two dimensional.
- The parameters are labelled `a` and `b`

2.2. Basis functions: USER TO SUPPLY

Now we need to choose a basis function. Do this by copying `basis.toy()` but fiddling with it:

```
> basis.vig <-
+ function (x)
+ {
+   out <- c(1, x , x[1]*x[2])
+   names(out) <- c("const", LETTERS[1:2], "interaction")
+   return(out)
+ }
```

Notes

- This is shamelessly ripped off from `basis.toy()`, except that I've changed the basis to be `c(1,a,b,ab)`.
- in the function, `out` is a vector of length four: `c(1,x[1],x[2], x[1]*x[2])`.

2.3. Data: USER TO SUPPLY

The data we have for the `.vig` example is a vector whose elements are the output of the code at the points specified in `val.vig`:

```
> head(z.vig)
```

```
[1] 4.171431 2.480450 5.115578 4.896623 4.421131 3.539162
```

```
> summary(z.vig)
```

```
   Min. 1st Qu.  Median    Mean 3rd Qu.    Max.
 2.480   3.398   4.160   4.373   5.095   8.054
```

3. Data analysis

The previous section showed what data and functions the user needs to supply. These all have a `.vig` suffix. This section shows the data being analyzed.

First we will estimate the scales to use:

```
> os <- optimal.scales(val=val.vig, scales.start=c(10,10), d=z.vig, func=basis.vig)
> os
```

```
[1] 2.662455 5.949278
```

So we can estimate the coefficients. But first we have to calculate the variance matrix and invert it:

```
> A.os <- corr.matrix(xold=val.vig, scales=REAL.SCALES)
> Ainv.os <- solve(A)
```

Given this, use `betahat.fun()` to get the coeffs:

```
> betahat.fun(xold=val.vig, d=z.vig, Ainv=solve(A), func=basis.vig)
```

```
   const          A          B interaction
1.258497  1.737033  2.375293  4.421692
```

The central function is interpolant:

```
> interpolant(x=c(0.5,0.5), d=z.vig, Ainv=Ainv.os, scales=os,
+ xold=val.vig, func=basis.vig, give.full.list=TRUE)
```

```

$betahat
      const          A          B interaction
1.258497  1.737033  2.375293  4.421692

$prior
      [,1]
[1,] 4.420083

$beta.var
      const          A          B interaction
const  0.3276688 -0.3110386 -0.3659008  0.3722797
A      -0.3110386  0.5486964  0.3757182 -0.6779246
B      -0.3659008  0.3757182  0.6450988 -0.6572957
interaction 0.3722797 -0.6779246 -0.6572957  1.3367391

$beta.marginal.sd
      const          A          B interaction
0.5724236  0.7407404  0.8031805  1.1561743

$sigma.hat.square
[1] 0.3483106

$mstar.star
      [,1]
[1,] 4.863723

$cstar
[1] -0.006422152

$cstar.star
[1] -0.005524694

$Z
[1] 0.04386695

```

And that's it, really.

A. Data generation

The data used in this study were created by directly sampling from the appropriate multivariate Gaussian:

```
> REAL.BETA <- 1:4
> REAL.SCALES <- c(3,6)
> REAL.SIGMASQUARED <- 0.3
> A <- corr.matrix(xold=val.vig,scales=REAL.SCALES)
> z.vig <-
+ as.vector(rmvnorm(n=1,mean=crossprod(REAL.BETA,apply(val.vig,1,basis.vig)),sigma=A*REAL.
```
